Radium.—Although radium was discovered in 1898, its use in medicine did not begin until about 1906. Today its use is confined practically to the treatment of cancer of the genital tract in women, cancer of the bladder in both sexes, to cancer of the external genitalia and the prostate in men, and to a few skin conditions. Usually radical surgery offers the best hope for the cure of malignant tumors, but if wide excision is unsuccessful and recurrence occurs, the use of radium is often advised. In cancer of the body of the uterus, which accounts for about 15 per cent of all cancers of the female genital tract, the results of radical operation ranged from 36 to 50 per cent of cures in a large group of statistics from many different sources over a period of three to five years. Where radium alone was used over a similar period in another group, the percentage of apparent cures was far lower, from 27 to 44 per cent. Experience in such cases during the late 1940's does not indicate that faith in the value of radium is increasing among those best qualified to speak for the medical profession.

Vitamins.—These are substances having a regulatory influence on body metabolism. Their presence is necessary to prevent certain pathological changes from taking place within the organism. Their identification is by alphabetical lettering, which has no relation to their chemical composition. See also section on *Avitaminoses;* separate article VITAMINS.

Visual Aids in Medical Training.—For several years medical teaching, especially in surgery, has been advanced considerably by the use of motion pictures. To this has been added television. Almost every technical procedure in medicine has been reduced to picture form, and films are available to the medical profession everywhere. These aids form a valuable supplement to the medical curriculum. Another striking advance has been of great visual assistance—that of medical illustrating in color. These illustrations have been produced mainly in the fields of anatomy, pathology, and surgery. Many of them are an education in themselves, since they portray the heart, lungs, gastrointestinal tract, breast, reproductive organs, and other anatomical parts in both health and disease, in such a manner as to give a close approximation to the appearance of actual living tissue.

PREVALENT DISEASES

Alkalosis.—Unlike acidosis, which has received a large share of attention in recent years, the condition known as alkalosis has been somewhat neglected. It is known now to be of common occurrence and to be occasionally the cause of great discomfort to the patient. Alkalosis is marked by concentration of bicarbonate above the normal. The condition of excess alkali may be owing to an undue amount of alkali introduced into the blood, unaccompanied by a compensating increase of nonvolatile acid, or to an excessive loss of acid, where no equivalent of alkali loss has taken place. The condition may arise from a too generous administration of alkalis and not infrequently is brought about by injudicious treatment of duodenal ulcer by what is known as Sippy treatment. It may be due also to an excessive use of bicarbonate in diabetic acidosis where insulin is being given. Other recognized causes are pyloric and intestinal obstructions. The common symptoms are headache, loss of appetite, drowsiness, persistent vomiting, myalgia, and excessive nervousness. In the occasional case there will be rapid respiration and even delirium. Muscle ache is one of the commonest symptoms. Even in apparently serious and alarming cases its treatment becomes effective by immediate withdrawal of the alkali and the use of intravenous injections of sodium chloride solutions. As a rule, prompt relief of symptoms will follow and no other treatment will be required.

Arthritis.—The common definition of arthritis is inflammation of a joint. The current term in use by nonprofessional persons is rheumatism. A host of varieties of this disease has been recognized for many years, but the underlying cause, in most cases, is unknown. The worst type and the most crippling is the rheumatoid variety—a chronic joint affection of unknown etiology affecting multiple joints, the disease being ac-

companied by many constitutional disturbances, such as debility and loss of weight. There is proliferation of granulation and connective tissue in and about the joints. Pain, limitation of motion, deformity, and stiffening of the joint are common. This is the disease which has produced so many helpless cripples who are condemned to a life in bed or in a wheel chair. Many are young persons, but the disease occurs at any age and in every walk of life. Over a period of many years the underlying thought among physicians has been to treat the patient by general measures, since no specific therapy was known.

During 1949 a hormone, first derived from the adrenal glands of cattle about 1939, was used by Kendall and Hench (see section on *Adrenal Glands*) in the specific treatment of joint disease. Originally this hormone was called Compound E, but the name has since become synonymous with cortisone. It has also been derived from ox bile. The use of cortisone in selected patients was startling from the first and its prompt action in affording relief in severe cases of joint disease seemed almost unbelievable. Persons almost completely crippled were able to move about freely. Relief from symptoms occurred after a few doses given intramuscularly. However, cessation of the specific treatment was soon followed by recurrence of symptoms, indicating the transitory nature of the drug's action. Very little of this invaluable substance can be produced and, since it cannot be made synthetically, a great difficulty is interposed to its wide use. The compound is extremely complicated, requiring nearly 40 distinct and separate steps before it can be obtained in a pure state. It may be said that the matter of its production, distribution, and clinical use is in an early and unfinished stage in 1950. As a possible substitute for cortisone, adrenocorticotropic hormone (ACTH) has been isolated, its action having been discovered in 1949. This hormone is extracted from the pituitary gland of the hog. The amount obtainable from this source—many thousands of animals—thus far has been insufficient to serve for more than clinical experimental purposes. It has not (1950) been produced synthetically. A limited use of ACTH in selected cases has met with marked success and there is hope that in time it will be produced synthetically in quantity, thus leading the way to the relief of millions of sufferers from chronic arthritis. See also separate article Arthritis.

Avitaminoses.—These conditions, often diverse and dissimilar, arise from lack of certain essential nutritive factors known as vitamins. The various syndromes encountered in these conditions vary in character and in severity. Vitamins are necessary for biochemical reactions taking place in the body. When these are interrupted, body function suffers.

Absence or deficiency of certain vitamins produces what are actual nutritional disorders. These deficiencies are not due to failure of the vitamin supply, since most of the substances exist in abundance throughout the United States and in many other countries which are important food producers. The principal deficiency diseases due to diet are the result of lack of vitamins A,B,C,D,G,K, and PP. Avitaminoses are produced by such factors as lowered food intake, digestive disturbances, and mental disorders. Of late years considerable importance has been attached to methods used in the detection of avitaminoses. Such should include analysis of diet, recognition of specific syndromes (symptom complex), analysis of body fluids, and therapeutic trials of known vitamins whose absence from the body is suspected. In many cases the last will prove the factor most to be relied upon for diagnosis. As a rule, the use of the correct vitamin in a particular case will result in prompt improvement.

Many foods lose much of their vitamin content in processing and, unless this is restored by enrichment, the use of these articles of diet cannot be relied on. An ordinary and varied diet will generally contain the vitamins necessary for body economy. Therefore an indiscriminate and habitual use of vitamins in pill form is unnecessary, since it is physiologically and economically unsound. While vitamin deficiency is common in some localities and is marked in the countries of Europe ravaged by the last war, it has been calculated that only one person in 25,000 of the general population develops vitamin deficiency so severely as to require hospital treatment. As a rule, the average person selects his diet unconsciously so as to provide an adequate intake of vitamins. Only when an individual chooses foods which are markedly different from average selections, is he likely to develop symptoms of deficiency. The daily amount of vitamins required for health will vary somewhat with age, sex, and activity. The amounts required of vitamins A and G do not vary with physical activity, but that of vitamin B complex does. The occurrence of pregnancy will change the vitamin requirements. Based on an average of 2,500 calories in food value, an adult of about 160 pounds will need: 5,000 units of A, 1.5 milligrams of B, 75 milligrams of C, 2.5 milligrams of riboflavin, and 15 milligrams of nicotinic acid. Based on these requirements, diet tables consisting of ordinary palatable food have been arranged. The common clinically recognized avitaminoses, many of which have been reproduced in animals, are listed here.

Avitaminosis A exhibits the clinical features of night blindness, cutaneous lesions, digestive disturbance, and disorder of the liver function. If present in the young, it exerts an unfavorable influence upon tooth development. The deficiency can be supplied from cod-liver oil, beef liver, kale, and other vegetables, or by the use of concentrated vitamin in unit dosage.

Avitaminosis C presents the symptoms of scurvy with loss of weight, tender and bleeding gums, and anemia. It is supplied by ascorbic acid, derived from fresh fruits, especially citrus fruits, and vegetables, such as tomatoes and cabbage, or by use of pills containing ascorbic acid.

Avitaminosis D produces symptoms and signs of rickets in children and osteomalacia in adults. These diseases are especially common in central Europe and in the northern United States. The condition is less likely to exist where exposure to sunlight is common. Marked deficiency in vitamin D results in changes in calcium levels and inorganic phosphates in the blood, which retards calcification of cartilage involved in bone growth. The most striking effects are seen in growing bone with the characteristic deformity. The exact amount of various vitamin requirements in adults is undecided. Dosage is often given in units, as international unit (I.U.). Large doses such as 60,000 units of some vitamins have been used. Fish- and cod-liver oil

and concentrates of these are in wide use for avitaminosis D.

Avitaminosis K occurs in infants and in adults with obstructive jaundice, sprue, and ulcerative colitis.

Avitaminosis B_1 has a classic example, long known to the world, in beriberi, seen mostly in Far Eastern countries. Vitamin B_1 is known also as thiamine. Lack of this substance may produce polyneuritis, cardiovascular dysfunction, and other disturbances. The lack is easily supplied by the administration of thiamine.

Cancer.—The word cancer is an all-inclusive term to indicate a malignant growth or tumor which causes a destructive invasion of the tissues, not necessarily neighboring ones, by actively vegetating epithelium. Since 1937 the subject of cancer has been much in the public mind and millions of dollars have been raised by various societies, groups, and foundations, engaged in studying the disease from the standpoints of cause, prevention, early diagnosis, and effective treatment. Education by means of public addresses, radio talks, publication of articles on cancer in lay magazines and journals, establishment of cancer clinics, and organization of public health programs have given detailed study and attention to arouse the public to the danger of delayed action in cancer cases and to the best means of combating the disease. It is interesting to note that perhaps the most extensive and earliest investigation concerning the occurrence of certain types of malignant disease was established as long ago as 1889 at the Johns Hopkins University. Since that time a record of bone tumors has been continued by Joseph C. Bloodgood (1867–1935) and his successors. These records, embracing thousands of cases accurately studied from a pathological and clinical standpoint, are available for examination by any physician. Other institutions have kept similar records concerning other tissues and organs, such as the breast, colon, and prostate, so that now the medical profession has accurate, statistical information concerning incidence of malignant tumors in all parts of the body, with figures relating to mortality with and without surgical interference. Despite all the scrutiny that cancer has received, the mortality is still shockingly high. The cause, while undiscovered, is perhaps within reach, in the opinion of some who speak with authority. See also separate articles CANCER; TUMOR.

Colds.—Much interest has been aroused since 1947 in the treatment of common colds by antihistaminic drugs. Phenandimine has been reported as effective in a large percentage of cases studied, when the attack was taken in hand promptly. One observer reported a series of 100 cases in which controls were used (employment of inert drugs or substances). In 24 hours, 54 per cent were cured and in all cases studied, where treatment was begun within 48 hours, 75 per cent were cured. In the control cases a like number were relieved of symptoms in 32 per cent of the cases. Side effects, such as drowsiness, dizziness, and headache, were noted in 26 per cent of the cases. By the use of benadryl in a series of 100 cases, 10 per cent were aborted and 95 per cent relieved of symptoms due to the inhibitory effect of the drug on the mucous membrane discharge. A number of other drugs have been used with reported success. The chief objection to the treatment is the drowsiness which makes it unwise for a person driving a car or flying a plane to use this means of relief. The subject continues under discussion among members of the medical profession.

Coronary Artery Disease; Organic Heart Disease.—High on the list of mortality rates from organic disease and collectively occupying first place is the group of organic diseases of the heart. Each year many cases of sudden death result from unsuspected heart disease, of which coronary occlusion is the commonest. Even in advanced form, coronary artery disease may present no clinical manifestations, and symptoms, even if present, are often unassociated with the heart. In recent years attention has been drawn increasingly to the possibility of the existence of coronary disease in all individuals in the so-called arteriosclerotic age (middle life) regardless of the apparent nature of the illness. Thus an elevated blood pressure, the presence of hypertension, a persistent bronchitis, an asthmatic attack, an obscure upper abdominal pain may be of significant import and may call for a careful examination of the heart. The modern treatment of early stages of coronary disease is rarely severely restrictive. Physical activities are, however, curtailed necessarily, reduction of weight is often imperative, and habits of living carefully studied. No startlingly new treatment has been advanced in therapeutics; rather the latest concept is early recognition of the condition for what it is, with prompt regulation of the way of life of the patient, instead of allowing him to go until the inevitable attack of thrombosis and occlusion takes place.

The role of digitalis and quinidine in organic heart disease is worthy of brief review. Although it is invaluable in heart disease, digitalis has its limitations and there are a number of puzzling factors connected with its pharmacological and therapeutic behavior which are still not understood. Of late years the scope of its usefulness is the more clearly apparent, perhaps because it has become recognized generally as both a heart stimulant and a heart depressant. Digitalis affects not only the heart but also the blood vessels and the kidneys. It has toxic effects on both the stomach and the intestines and not infrequently on the heart itself. Occasionally, if administered injudiciously, it may prove a fatal drug. Its cumulative action has long been recognized. Digitalis is useful in congestive heart failure, in auricular fibrillation, in pulmonary edema, and in valvular defects. It is useless in most of the nervous manifestations connected with heart disease and is not advised in the cardiac symptoms of hyperthyroidism. There is almost no satisfactory evidence to support its use in pneumonia, but in certain infectious diseases, such as rheumatic fever and diphtheria, it is said to be of some value. If not well borne by mouth, it may be given by rectum or intravenously.

Of the somewhat newer drugs used in cardiac disease much interest has been aroused in quinidine, now recognized as of great assistance in certain types. Because of its untoward results, at one time the use of quinidine was practically abandoned, but satisfactory results in certain cases have been established beyond question. The principal indications are in auricular fibrillation and auricular flutter in association with advanced myocardial and valvular disease. It should be prescribed neither in coronary thrombosis nor in extensive myocardial involvement.

The drug may be given intravenously, if not well borne by mouth.

Diabetes (modern concept).—It has been assumed not infrequently that since the discovery of insulin diabetes has been a closed book. This is not so, however, and diabetes mellitus remains in the realm of controversy. Its etiology is still the subject of intensive research in connection with problems arising in studies of metabolism and biochemistry. Many of its complications are puzzling to the clinician. Of late years the discovery of the fact that tens of thousands of diabetics are going about their business, eating what they please, in complete ignorance of their affliction is a challenge to the medical profession. This has led to the inauguration of diabetic diagnostic clinics and to publication to the general public of methods of self-testing for sugar in the urine.

The simplest definition of diabetes remains unchanged: a disease of abnormal carbohydrate metabolism. In more explicit terms it is a primary, incurable inability of the tissues to utilize glucose properly because of insufficient production of insulin in the pancreas. The definition makes no mention of complications, such as acidosis, ketosis, arteriosclerosis, and coma, and assumes that insulin corrects only the abnormality in carbohydrate metabolism.

It has been doubted even that diabetes is caused by a lowered supply of insulin alone. In this connection an interesting fact should be cited, that patients who have undergone a total removal of the pancreas usually require but a moderate daily dose of insulin, while many diabetics need a far greater amount.

Under modern concepts and management, which accepts a basic physiology, a knowledge of the characteristics of the insulins, and a properly regulated diet, it has been stated that at least 95 per cent of diabetics can be well controlled and that the remaining small per cent developing unusual or dangerous manifestations may be managed by a more rigid application of the basic principles of diabetic regime. The incidence of ketosis, acidosis, and other untoward symptoms may be regarded as attempts on the part of the body to restore to the normal a mechanism thrown out of gear by the deficiency in carbohydrate metabolism and by the inability of the body cells to oxidize glucose. The essentials of diabetic management are to keep the patient symptom-free, to keep the blood sugar and the urine sugar as near normal as possible, to avoid severe insulin reaction, and to arrange the diet and environment approaching the normal, bearing in mind compatibility with the primary objectives mentioned, and lastly, to educate the patient in prevention of coma. Except for minor variations these essential factors are agreed upon by the foremost authorities, although a few observers hold that the blood sugar level and the presence of sugar in the urine are of small moment, if the patient maintains his weight and is free from acidosis.

Epidemiology.—Epidemiology may be defined as the study of occurrence and distribution of disease, usually epidemic and endemic, but at times broadened to embrace all types of disease. As a result of World War II the study of epidemic disease was undertaken on a worldwide basis and the term "global epidemiology" came into current use. It was recognized then that maintenance of the health of troops in all parts of the world was of first importance to the success of military operations, which might extend from the frozen North to the equatorial belt. In the past such diseases as cholera, malaria, plague, and typhus in its many forms had in great part often determined the success or failure of battles and wars.

At the outbreak of war, surveys of all countries were made by the Medical Intelligence Division of the United States armed forces and approximately 190 areas were studied exhaustively from a sanitary standpoint. Perhaps the most significant lesson of malarial research was to emphasize the highly specific character of malaria in many localities. Measures of control applicable to one locality were not always successful in another. Information was gleaned from all possible sources, both written and other, and the evaluation of data proved of the utmost value. The sanitary surveys covered geography, climate, health service, water supply, disposal of sewage, prevailing insects, food and dairy products, diseases spread through the intestinal and respiratory tracts (including those spread by contact and by means of such insects as ticks and mites), and nutritional diseases. Since practically every corner of the world was under scrutiny, there was collected a vast amount of information which never before had been assembled and documented. This has been disseminated and should have a profound and practical effect on prevention of disease.

Tropical Diseases.—One of the most striking and significant portions of the report (see *Bibliography*) is that indicating the world distribution of the so-called tropical diseases, of which the most important are listed here.

Cholera was found to exist nowhere in the world except in two highly endemic areas of eastern China and south and central India.

Dengue was reported in many large endemic areas of western China, the East Indies, northern Australia, the coasts of the United States and South America, the coast of Africa, central Africa, India, and the Near East.

Filariasis was noted in many large areas of west China, the East Indies, West Indies, the northern coast of South America, and nearly all of Africa except the Sahara Desert.

Malaria was highly endemic in west China, the East Indies, Central America, northern South America, much of the Near East, almost all of Africa, and a great part of Asia. This is probably the widest distribution of any disease known to man. The moderate and low endemic areas comprise a large portion of the remainder of the world. Areas in which malaria is not found are Central Asia, Central and South Australia, the Sahara Desert, a large portion of North America, and the Andes region.

Plague was discovered in western Asia, parts of South America, the coasts of Africa, and India.

Relapsing fever, occurred in nearly all of Asia, western United States, most of Africa, and some parts of South America. It was not reported in Australia nor in the East Indies.

Trypanosomiasis (sleeping sickness) was found only in Central and South America, west coast of Mexico (Chagas' disease), and west central Africa (African sleeping sickness).

Typhus was noted in practically all of Asia, southeastern United States, Mexico, west coast of South America, most of Europe, and the coasts of Africa.

Yaws were found in the East Indies, North Australia, Central America, northern half of South America, and central Africa.

Yellow fever was encountered in central South America, especially Brazil (east coast), west coast of Africa, and central Africa. Yellow fever has been present and can be epidemic in the vector areas covering west China, west coast of Africa, all of South America except Argentina, all of Africa except the Sahara, south central Europe, India, and the southeastern United States. This deduction is made because of the prevalence of the insect vector of yellow fever in these areas.

Gonorrhea.—Since the discovery of the antibacterial action of the sulfonamides and the antibiotic action of penicillin and similar derivatives of certain molds, the treatment of gonorrhea has been almost revolutionized. Apparently there is no true immunity against gonorrhea, and it is probable that while some immunity is built up by the patient, this is limited largely to the infected mucous surfaces. This immunity, such as it is, seems to be achieved more readily in the male than in the female. Even without treatment the disease is self-limited. The modern treatment of gonorrhea centers about the sulfonamide drugs. In the opinion of most clinicians, sulfonamide itself is not appropriate, since the rate of cure is low and its toxicity high. Almost all authorities recommend the use of sulfathiazole. It is not known precisely when a cure takes place, but patients who seemingly are uncured in five days are regarded as drug refractory. Many of these are cured by a second course of medication. If they remain uncured after a second course, such patients as a rule are not given a third. Excellent results seem to be attained by the use of sulfathiazole (20 grams) during a period of five to seven days. Severe drug reactions are said to occur only in about one per cent of cases, although some patients appear to have an idiosyncrasy for any sulfonamide drug. One plan is to give four grams of sulfathiazole powder daily in divided doses over a period of five days. If symptoms persist, after a rest period a second course is given. In some cases prolonged artificial fever (heat cabinet) is used in connection with specific medication. In resistant cases penicillin is frequently prescribed and seems to be particularly beneficial in a large proportion of those cases in this category. Many clinics and also the National Research Council have reported good results in the use of penicillin in combination with chemical treatment. The same routine has been advised in women as in male patients. In addition, local treatment and treatment of complications is often necessary. Statistics as to prompt cure of gonorrhea by modern methods vary, but the rate is probably in excess of 80 per cent.

Infectious Hepatitis.—During World War II, infectious hepatitis was a serious factor in morbidity among newly inducted troops. It became the subject of exhaustive inquiry on the part of medical authorities in the armed forces. The etiologic agent is a filtrable organism (agent or virus) resistant to heat at 56°C. It is not affected by chlorination. It is contained in the blood and feces of the patient. The virus is believed to be spread by water, food, and milk. An attack of hepatitis usually protects the individual from further invasions.

Poliomyelitis (present concept).—Anterior poliomyelitis or infantile paralysis is an acute infection of the anterior horns of the spinal cord by an unknown virus. It has been described as a group infection confined to intimate associates. The carrier state may develop within a short time. Some agency other than man may be an important contributor to the spread of the disease. Since 1890 poliomyelitis has changed from a sporadic to an endemic disease. Why it remains dormant for approximately eight months of the year and then flares up into an explosive epidemic has not been determined. The disease has an uncertain progress in the individual and may result merely in muscular weakness, from which recovery is easy, or it may proceed rapidly to complete paralysis, including the respiratory muscles, ending in death. The causative agent is unknown, but is recognized as a virus, since the disease can be transmitted to monkeys. The virus is presumed to enter the body through the nasal passages, but nothing further concerning it is known. The disease is not particularly contagious and the mortality rate is lower than most people think, certainly less than 15 per cent. It is believed that a considerable number of persons acquire poliomyelitis in mild form, but recover without a diagnosis having been made.

Since about 1940 it has been a subject of wide controversy and of widespread alarm. Its controversial aspects are mainly concerned with what is known as the Kenny treatment (Elizabeth Kenny 1886–). This treatment has not received the unqualified support of orthopedic surgeons, but it has earned great popular approval and much professional support. The treatment is begun as soon as a diagnosis is made. The patient is put to bed on a firm reinforced mattress (bed boards). A footboard is also used to keep pressure of the bed clothing from the feet. If muscular spasm is present, hot fomentations are applied to the affected muscles and passive motion is inaugurated once a day or oftener. As soon as joints can be moved without pain, muscle re-education is begun while the patient is still in bed. The use of a respirator where the respiratory muscles are involved in the paralysis is not a part of the Kenny treatment. In many cases the treatment outlined must be supplemented by the use of apparatus adapted to a specific purpose and used under the supervision of an orthopedic surgeon. In prevention of the disease the use of attenuated virus has by no means met with unanimous professional approval and by some is considered extremely dangerous.

Shock.—This is still regarded as a major problem in medicine and surgery. It is always a menace in accidents arising from present day methods of transportation and modernization of our way of life. It can be treated only by adoption of the physiological application of prevention. Shock has always been difficult to define adequately and at one time it was subdivided according to causation, that is, shock following such circumstances as burns, injury, surgical operation, or hemorrhage. But shock should be regarded as including a great variety of conditions, the common feature being a progressive failure of the circulation. Physiologically speaking, it has been held that shock is not present, unless death is to be expected, if appropriate treatment is withheld. In every clinical case, however, shock must be treated as if this condition were actually present. Shock was once defined by Samuel D. Gross (1805–1884) as a

rude unhinging of the machinery of life, a definition which expresses well its clinical aspect. The latest concept is more detailed and the definition has been accepted that it is a peripheral circulatory failure occurring from a discrepancy in the size of the vascular bed and the volume of blood (or fluid) actually within the vessels. The present trend is to classify shock under three heads: (1) hemotogenic, which is produced by physical injury, hemorrhage, burns, and loss of body fluids from any cause; (2) neurogenic, which is caused by dilatation of the blood vessels due to nervous stimuli, and usually transitory, of which examples are to be seen in spinal anesthesia, manipulation of viscera in surgical operations, and fainting; (3) vasogenic, where the blood volume may be normal, but the blood pressure is extremely low, of which anaphylaxis (serum sickness following serum therapy) and the condition induced after an overdose of insulin may be cited as examples. Early treatment of shock and its anticipation are extremely important, and nothing should be done or left undone that will aggravate the condition. Measures in use to combat shock are: relief of pain by opiates, elevation of the feet, inhalation of oxygen, application of external heat, and early use of blood substitutes and blood transfusions up to a maximum of six pints of whole matched blood.

Tuberculosis (modern concept).—Pulmonary tuberculosis in man has existed probably ever since he began to live a communal life. Until near the end of the 19th century the disease occupied a high place in all mortality tables and the so-called white plague was a serious menace to society. Since 1918 this threat has become less and less grave in the United States. This has not come about by any specific treatment, but from a combination of factors, each one of which has contributed to lowering of morbidity and mortality. Two characteristics are concerned in tuberculosis: the tubercle bacillus and the human host. At least four types of the bacillus are recognized: the human, the bovine (cattle), the avian (birds), and the ichthyic (fish).

In man the disease is always due either to the human or to the bovine type, and the younger the person, the oftener the bovine type is present (38 per cent of infants). Adults seldom become infected with the bovine variety, which in human beings tends to die out after a few years. In the course of the disease, the bacillus produces a protein (tuberculin). All tuberculous subjects are sensitive to the injection of even the most minute quantities. Avenues of infection are said to be nearly 96 per cent through the lungs, the remaining 4 per cent being through such parts as the intestine, nose, or conjunctiva. It is easily disseminated by contact and is to a high degree a family disease. It is not hereditary despite reports to the contrary. It is quite probable that nearly every human being in civilized countries becomes infected at one time or another with tuberculosis and that the manifestations of the disease are largely matters of chance, environment, economic stability, or other factors. Certain occupations have a high incidence. Since the last quarter of the 19th century, the mortality has declined by 50 to 75 per cent, and this has been achieved by generalized pasteurization of milk, isolation of consumptives, popular education in health measures, prophylactic care of children, wide use of chest X-rays for diagnosis, and betterment of economic conditions. In many cases radical surgery has proved a lifesaving measure in selected individuals.

Viruses and Virus Diseases.—Caution is necessary in referring to virus diseases as such, and the term is sometimes used loosely. At one time a number of infectious diseases were thought to be produced by viruses and many of these are known now to be due to bacteria, protozoon parasites, and spirochetes. There still remain a fair number of diseases whose causal agents are unknown. Since these agents can be passed through earthenware filters impervious to ordinary bacteria, such are referred to generally as filtrable viruses, ultrabacterial viruses, and ultramicroscopic viruses. It is well to bear in mind that the word virus is not synonymous with poison, but means here that a germ or microbe is too small to be demonstrated properly or convincingly. Excluding the plant diseases, some of the common virus diseases of man and animals are: hog cholera, rinderpest, swine pox, cowpox, smallpox, varioloid, chickenpox, several varieties of encephalitis (lethargic, Japanese, Australian X-disease), poliomyelitis, rabies, distemper of dogs, mumps, measles, parrot fever (psittacosis), common colds, influenza, and trachoma. Other diseases, both insect-borne and bacterial, among which differences of opinion exist as to their being catalogued as virus diseases, are: African horse fever, pappataci fever, dengue, yellow fever, equine encephalitis, typhus fever, Rocky Mountain spotted fever, trench fever, heartwater disease, Oroya fever, and pleurodynia. It is believed that some viruses are so small that they are not capable of measurement by means of the most powerful microscopes. Not all are so minute, however, as to defy visualization and certain cells have been observed to contain what are known as inclusion bodies. What relation these bear to viruses is not known. (See section on *Immunity*.) See also SURGERY and separate articles on the various medical sciences and diseases.

Psychosomatic Medicine.—Up to about the year 1930 our knowledge of the psychoneuroses was centered largely around certain syndromes or groups of symptoms, unaccompanied by any well grounded system of treatment. Treatment was largely empirical and not conditioned to the needs of the individual patient. In the years that followed, a clearer understanding has come about and this has aided, to a gratifying extent, the evolution of a plan of treatment aimed at correcting, in individual cases, the basic causative factor. Much of this has been achieved through the work of Sigmund Freud (1856–1939) and Adolf Meyer (1866–). Such plans are often referred to as belonging to the field of psychosomatic medicine.

Belief in the psychic origin of mental and physical ills is not at all new but up to the close of the 19th century it encountered much opposition. Not until the significance and purpose of symptoms and syndromes were elaborated in later years was it understood that individual conduct can often only be explained on the basis of fixed ideas which govern it unconsciously. It has been emphasized that psychosomatic unity of the individual must be present for normal functioning of the body. Since 1940 it has become more and more apparent that the physiologic function of organs and the organs systems are closely allied to the state of mind of the individual and that even tissue changes may occur in an organ so affected. Such changes are some-

times referred to as "organ neuroses." The psychoneuroses are subjective chiefly even though incapacitating. A victim of psychoneurosis is not out of touch with realities and there is no intellectual deterioration nor are delusions and hallucinations present. Several types of psychoneuroses are recognized, the most generally agreed upon varieties being: hysteria, neurasthenia, compulsion neurosis, anxiety states, and organ neuroses. The clinical types are not regarded as completely separated by an unchanging entity classification. The predisposing factors which bring about the condition are influences on the mind itself through conscious and appreciated mental problems that cause worry and anxiety, or from deeply seated mental conflicts which are a part of the unconscious or subconscious mind. In the ordinary matter of living there is a constant adjustment of the personality to the environment. Inability to make adjustments to environment produces a mental conflict or a mental compromise and here are the important factors whose comprehension are so necessary to a complete understanding of the origin of the psychoneuroses. For proper diagnosis and adequate treatment, the driving forces present, the type of symptoms observed, and a knowledge of the social background as well as the manner in which these symptoms have developed, must be studied. The forces or "drives" governing conduct may be fear, love, hate, sex, hunger, herd instinct, and so on. The drives, or urges, are striving constantly for expression and their total suppression is impossible. A "complex" or idea arising from a primary urge must express itself in a conscious way. Because this may be repugnant to the individual a "conflict" may arise, with resulting tension. In compensation the complex may be by-passed into some indirect expression or manifestation. A complex has been defined as a group of ideas with associated strong emotion. When it is repressed, it becomes, by dissociation, a vague fear or anxiety, or perhaps a compulsion neurosis, or a phobia.

In hysteria the reactions may be extremely varied. Symptoms may involve the motor, sensory or visceral fields. Bodily disturbances may be permanent, and paralysis, muscular contractures, catalepsy, deafness, loss of voice, and loss of memory are common. In time, if the condition is not benefited by active therapy, tissue changes may occur. Such reactions as have been mentioned have their origin in maladjustment situations often dating back to childhood and, because of unstable personality, may be difficult to treat.

Neurasthenia and hypochondriasis are closely associated. The use of the term neurasthenia has been abused. The condition is actually a state of mental and physical fatigue. Unlike ordinary fatigue it comes with very slight exertion and that of a particular nature. There is also poor memory, inability to concentrate, and nervous irritability. The symptoms are so numerous as to include practically every sensation, the commoner ones being general aches and pains, pressure symptoms, especially those referred to the interior of the head, backache, loss of appetite, nausea, dizziness, and circulatory disturbances. There is often discouragement and a state of low spirits, with insomnia. If the symptoms center around some particular organ or organ system the patient's attention may become fixed upon this deviation which to him portends a serious condition and he becomes a hypochondriac. In general the symptoms of neurasthenia are the result of emotional reaction arising from long conflict with the difficulties of life. These may be of different kinds such as give rise to resentment, feelings of insecurity, and those of deprivation.

Compulsion neurosis is known also as psychasthenia and is characterized by obsessions, compulsive acts, and nervous tension. There may be doubts, fears, phobias, and sometimes rituals (hand washing). The underlying mechanism is some innocent idea which has been substituted for a deeper but unacceptable desire. The patient wishes to avoid the obsessive thought and therefore substitutes something else. Such conflicts often arise in childhood.

Anxiety states show symptoms that are manifestations of acute fear and are referred to as "attacks." Between attacks the patient may be normal. Intense anxiety is shown by heart symptoms, chest and gastric symptoms, etc.

In organ neuroses the physiological function is disturbed. If intense intellectual energy cannot be dissipated in the ordinary way it tends to provoke symptoms in visceral organs and endocrine glands. If the gland or organ disturbance is only temporary, no disease will be found, but if it becomes permanent, organic disease may result. In all psychoneuroses much can be achieved by prevention but in late and well defined cases psychiatric treatment must be relied on.

HAROLD WELLINGTON JONES,
Former Director, Army Medical Library; Editor, "Blakiston's New Gould Medical Dictionary."

MEDICINE DANCE, a common practice among the American Indians; dances being conducted by the medicine men of the tribe for various purposes, and in preparation for different events, like warfare, and the hunt. Both in the dance before a battle and in the conflict itself the medicine chief is the one man most worthy of consideration. If war takes place, he courts the thick of the fight if for no other reason than to show his immunity from danger. The funeral dance of the Yaqui tribe is a representative example of the medicine dance; the chief medicine man arranging the ceremony, which ensures the safe passage of the dead to the spirit world. The dancers to the number of half a hundred appear in the center of the assembled tribal gathering, naked except for a cloth about the loins. Their bodies are painted in imitation of skeletons. Over their heads they wear masks fringed with long horsehair, dyed in many hues, eyelashes and eyebrows hang over the rudely designed faces, and beards reach nearly to the waist. On their legs they fasten strings of rattles cut from rattlesnakes,, and the sound of these is most gruesome to the spectators. Each dancer carries two knives, with which he gesticulates violently in imitation of the act of slaying imaginary enemies.

MEDICINE HAT, city in the Province of Alberta, Canada, on the South Saskatchewan River, about 185 miles southeast of Calgary.

It is in a high, dry area (elevation 2,185 feet; precipitation variable but frequently below 12 inches) originally devoted to ranching and dry farming but now coming under gradual improvement by irrigation under a joint scheme of the Dominion and provincial governments. It is important also as a railway center, being a divisional point on the main line of the Canadian Pacific Railway where the Crow's Nest line branches off into southern Alberta and southeastern British Columbia. It was to the coming of the railway in 1883 that the town owed its birth. It is also on the Trans-Canada Highway and has a Trans-Canada airport with daily flights. The early discovery of one of the largest of known natural gas fields underlying the district, the product being almost pure methane, gave industry an immediate impetus. ("Medicine Hat has all hell for a basement" was a comment of Rudyard Kipling when present at the "blow-off" of a new well in 1902.) There are also large deposits of lignite in the vicinity. Flour and feed milling, grain elevators, foundries, lumber mills, and machine shops are located here. The city handles the gas supply as well as its own water filtration and electric power and lighting systems. It has three business colleges, in addition to public and high schools and an academy. There are 22 churches, a hospital, a daily and weekly newspaper, a radio station, four banks, a chamber of commerce, and an industrial commissioner. The early population was recruited from Ontario, the Maritime provinces, and Great Britain, with a small infusion of Russo-Germans.

The curious place-name "Medicine Hat" is a translation of the Blackfoot Indian word "saamis" meaning the headdress of a medicine man. Various explanations of its application have been offered, several based on Indian legends, and one on the shape of a hill east of the town. A generally accepted one is that of a fight in which a Cree medicine man lost his professional headgear to a Blackfoot in the river. This and other local folklore, including the region of the Cypress Hills to the southeast —a rendezvous of the Cree and Blackfoot Plains Indians as well as of the Sioux under Sitting Bull after the defeat of Custer—have been collected in a brochure by F. W. Gershaw, a member of the Canadian Senate. Pop. (1951 est.) 12,000.

Consult Wilfred Eggleson's *High Prairie.*

MEDICINE MAN, among the American Indians, South Sea Island tribes and other peoples, a man supposed to possess mysterious healing powers. Among most of them the medicine man occupies much the same position as that held in civilized communities by two of the learned professions—medical and clerical. The medicine man is both priest and physician, and is at once the repository of all that a tribe knows, fears and believes. In very low stages of human development, however, he is at best only a magician, dealing in terrors, possessed of occult powers, but laying claim to no special medical knowledge. Thus, among the aborigines of north Queensland, the tribal doctors do not attend the sick, an invalid being cared for by wife or mother. They are not ostentatious, a medicine man being distinguished by no insignia save a small bag for his talismans, death charms and other "credentials." Among the North American Indians medicine men are treated with great respect, and form a secret society with exclusive privileges and "exercise a terrible influence in degrading the people." It is curious to find that, as in Australia, the Indian medicine men are chiefly concerned to do positive harm. In cooperation with good and bad spirits, they bring about the deaths of men or dogs at a distance. Among the Ojibways they are a kind of broker in vengeance, and a coward or a hypocrite who wishes to be covertly avenged upon an enemy will bribe his tribal medicine man to employ the medical attendant of his victim. Then, if the victim dies, the instigators remain unsuspected, and the actual perpetrator of the crime probably goes scot free. Indian medicine men affect to suck out poison from a patient's body, or they cough up an arrow point or small, sharp piece of stone or bone which they suppose has been transferred from him to them by the evil spirit of another sorcerer. The medicine men of the Eskimos are even more extravagant in their pretensions. They profess themselves able to change into wood, stone or animal, or even to walk on the water, or to fly, but they make a condition, which is that "no one must see them."

MEDILL, mĕ-dĭl′, **Joseph,** American journalist: b. near St. John, New Brunswick, Canada, April 6, 1823; d. San Antonio, Tex., March 16, 1899. Having early removed to Massillon, Stark County, Ohio, he was admitted to the bar in 1846, practiced at New Philadelphia, and in 1849–1851 published at Coshocton the *Republican,* a Free-Soil paper. In 1852 he established at Cleveland the *Daily Forest City,* a Whig organ, which in 1853 was united with the *Free Democrat* and called the Cleveland *Leader.* In 1855 he sold his interest in the *Leader,* removed to Chicago, with two partners purchased the Chicago *Tribune,* advocated radical antislavery measures and supported Lincoln in 1860. He was a member of the Illinois constitutional convention of 1870; United States civil service commissioner in 1871 and in that year was elected mayor of Chicago. In 1874 he became editor in chief of the Chicago *Tribune,* in which position he remained until his death. It was largely due to his individual efforts that the city of Chicago was selected for the World's Fair of 1893.

MEDINA, mĕ-dē′nȧ, **Harold Raymond,** United States jurist: b. Brooklyn, N. Y., Feb. 16, 1888. Educated at Princeton University (A.B. 1909), he went on to Columbia Law School and gained his bachelor of laws in 1912. In the same year he was admitted to the New York bar and became associated until 1918 with the law firm of Davies, Auerbach and Cornell. From 1918 to 1947 he was senior member of the firm of Medina and Sherpick, and taught at Columbia as lecturer in law (1915–1917), associate in law (1917–1925), and as associate professor of law (1925–1947). As a practicing lawyer he was counsel for Herbert Singer, the only defendant acquitted during the trial of officials of the Bank of the United States (1931), and he successfully defended Anthony Cramer

in the first treason case decided by the United States Supreme Court (1945). As both judge and lawyer he shared in effecting numerous reforms in court procedure.

In 1947 Medina was appointed by President Truman as judge on the United States District Court, Southern District of New York, and from January to October 1949 he presided over the nine-month trial of 11 Communists charged with and later convicted of conspiracy to teach and advocate the overthrow of the United States government by force and violence. In June 1951 the Supreme Court upheld the jury's conviction of the Communists as well as Medina's handling of the trial and the sentences he imposed. On June 11, 1951, he was appointed to succeed Judge Learned Hand (q.v.) on the U. S. Circuit Court of Appeals for the Second Circuit.

A prolific author and compiler in the field of law, Medina's works include: *Pleading and Practice Under New Civil Practice Act* (1922); *Cases on Federal Jurisdiction and Procedure* (1925); *Cases on New York Pleading and Practice* (1928); *Selected New York Practice Statutes* (1928); *Cases and Materials on Jurisdiction of Courts* (1931); *Medina's New York Civil Practice Manual* (1932); *Digest of New York Statute and Law* (1941); and *Summary of New York Pleading Practice and Evidence* (1941).

MEDINA, Sir John Baptist, Spanish portrait painter: b. Brussels, 1659; d. Edinburgh, Scotland, Oct. 5, 1710. The son of a Spanish officer who had married and settled in Brussels, then under Spanish rule, Medina studied painting in his native city under François Duchâtel. In his youth he married at Brussels Joanna Maria van Dael who bore him many children. Going to London in 1686 he established himself as a portrait painter, quickly gaining a reputation and many noble sitters. Two years later, one of his patrons, the munificent third earl of Leven (David Melville, 1660–1728), induced him to settle in Scotland; a subscription of £500 was collected to enable him to practice in Edinburgh. Accordingly he moved there with his large family. The antiquary George Vertue tells that he brought with him from his London studio "many postures for heads, the draperys painted—only to put the faces to them, cover'd them over with water-colours." By these mass production means he managed to paint a considerable number of paintings in a short time. He received so many commissions from the Scottish nobility that he was called "the Kneller of the North." He painted 20 portraits for the earl of Leven, including three of the earl himself. In Surgeons' Hall of Edinburgh's Royal College of Surgeons are several portraits of fellows of the college. The duke of Queensberry, as lord high commissioner of Scotland, knighted Medina in 1707, he being the last man in Scotland to receive that honor before the passage of the Act of Union the same year. He is also remembered for his drawings illustrating the Jonson edition of Milton's *Paradise Lost,* done during a visit to England in 1705. One of his sons, John (d. 1764), also practiced as a portrait painter, as did the latter's son John (1721–1796).

MEDINA, José Maria, Central American politician: b. Honduras, about 1815; d. Santa Rosa, Feb. 8, 1878. He was president of Honduras from 1862 to 1863, and was re-elected in 1864–1866 and in 1870. The war with Salvador in 1871 disturbed his successful administration and at the next election he was defeated by the Liberal Party. Defeated again by Leiva in 1874 Medina raised an unsuccessfull revolt in 1875–1876 and in 1877 a second revolt was punished with death by court martial.

MEDINA, José Toribio, Chilean bibliographer, scholar and author: b. Santiago de Chile, Oct. 21, 1852; d. 1930. He received his education at the National Institute and the University of Santiago, being graduated in law at the latter institution in 1873. At the age of 22 he was appointed secretary of legation at Lima. In that city he made investigations in the archives and in 1878 after his return to Chile he published a history of Chilean literature. Already in 1874 he had published a metrical translation of Longfellow's *Evangeline.* In the War of the Pacific, Medina served in the army and at the close of the war was made judge in the provinces ceded by Peru. He was made secretary of legation at Madrid in 1884 and here also he delved into the Spanish archives dealing with the Spanish in America and especially the history of Chile. He returned to his native country after several years' residence in Europe. He went abroad again in 1902 and also visited the United States to make further historical studies. Medina's great work is the *Biblioteca hispano-americana, 1493–1810,* 7 vols. (1898–1907), which contains notices of 10,000 works.

MEDINA, Vicente, Spanish poet: b. Archena, Murcia, 1866; d. 1936. Of humble origin, he earned wide fame after publication in 1898 of his *Aires murcianos* which profoundly influenced the character of regional poetry in Spain and Spanish America. He was not interested in mere depictions of the picturesque, or of physical and social aspects of an environment. He strove, rather, to capture the soul of the people through delineation of emotional conflicts and elemental human qualities.

MEDINA, mĕ-dē'nȧ (Arab. al-Madina), city, Arabia, 500 miles southeast of Palestine, 210 miles north of Mecca and about 120 miles from the Red Sea coast. It is reached from Damascus by an 820-mile railway journey. The city is celebrated for containing the tomb of Mohammed, whence it ranks second to Mecca as a pilgrimage resort of Islam. It is situated in the most fertile spot of all Hejaz, the streams of the vicinity tending to converge in this locality. An immense plain extends south from it; in every direction the view is bounded by hills and mountains. The town forms an oval, surrounded by a strong stone wall, 30 to 40 feet high, that dates from the 12th century, and is flanked with towers, while on a rock, at its northwest side, stands the castle. Of its four gates, the Bab-al-Salām, or Egyptian gate, is remarkable for its beauty. Medina has no large buildings except the great mosque, two smaller ones, a college and public baths. The houses are of stone, two stories high. Beyond the walls of the city, west and south, are suburbs consisting of low houses, yards, gardens and plantations. These suburbs have also their walls and gates. The mosque of the prophet stands at the east side of the city and resembles that at Mecca on a smaller scale. Its court is almost 500 feet in length, the dome is high and the three minarets picturesque. The tomb of the prophet, who died and was buried here in 632, is enclosed with a

screen of iron filigree, at the south side of which the pilgrim goes through his devotions, for all of which he pays, but is consoled with the assurance that one prayer here is as good as a thousand elsewhere. The tombs of Fatima (Mohammed's daughter) and abu-Bekr (father of his wife Aisha), and of Omar, the first caliph, are also here. The mosque dates from the period of Mohammed, but has been twice burned and reconstructed. Omar I and Othman ('Uthmān) both enlarged the original simple brick structure. It was again enlarged by the Caliph Walid (al-Walīd), so that it enclosed the three tombs. It was destroyed by lightning, probably about 850, and the graves almost forgotten. In 892 the place was cleared up, the tombs located and a fine mosque built, which was destroyed by fire in 1257 and almost immediately rebuilt. It was restored by Khaid Bey, the Egyptian ruler, in 1487. It is estimated that one third of the pilgrims to Mecca go on to Medina, the pilgrimage to which may be performed at any time of the year. In the time of Ptolemy the town was known as Lathrippa. There never was much population until the place acquired fame as a resort for pilgrims. From 1814 Medina had been the capital of the north pashalic of Arabia. In June 1916 Husein-ibn-Ali (Ḥusayn ibn-'Ali) proclaimed his independence of Turkey. Mecca thus, with the founding of the new kingdom of Hejaz, was lost to the Turks; Medina held out, however, until Jan. 13, 1919, when the Turkish garrison under Fakhri Pasha surrendered to the Emir Abdullah, the representative of King Husein of Hejaz. In 1924 it was occupied by Wahabis under ibn-Saud, who later established the Kingdom of Saudi Arabia (q.v.). Pop. (1951 est.) 12,000. See also MOHAMMED.

Consult Burton, Sir Richard Francis, *The Pilgrimage to Al-Medinah and Meccah* (London 1855); Twitchell, K. S., *Saudi Arabia* (Princeton 1947).

MEDINA, mĕ-dī'nȧ, village, New York, in Orleans County; altitude 530 feet; on the New York Central Railroad; 41 miles west of Rochester. It is on the line of the old Erie Canal, now the New York State Barge Canal.

Surrounding the village is a fertile agricultural area, producing field crops and fruits, especially grapes and apples. Like most towns in this region, Medina has the canning of fruits and vegetables as a basic, though seasonal, industry. More stable employment is provided by furniture and textile factories, foundries, and machine shops. Many of the buildings in the village are red sandstone which was quarried in the vicinity from the early days of settlement until late 19th century. There is a public library.

Medina was first settled in 1803 and incorporated in 1832. Its government is administered by a mayor and council. The water supply system is municipally owned. The electric power and light are purchased from a private company. Pop. (1940) 5,871; (1950) 6,179.

MEDINA, city, Ohio, and Medina County seat, 28 miles south of Cleveland; altitude 1,086 feet, on the Baltimore and Ohio and the Akron-Canton and Youngstown railroads; has an airport. It produces furnaces, aluminum casting, pickles and relishes, honeybee supplies, and honey products. It has a public library, and public and parochial schools. The government is by mayor and council. Pop. (1940) 4,359; (1950) 5,086.

MEDINA SERIES, *in geology,* a term introduced by the New York Geological Survey for a subdivision of the Upper Silurian series, apparently the base of that system. It is named from Medina, N. Y.; occurs throughout the Atlantic states; and includes shales, conglomerates and sandstones. For the Medina sandstone see LEVANT.

MEDINA-SIDONIA, mȧ-thē'nä-sē-thō'nyä, city, Spain, in the province of Cádiz, 19 miles southeast of Cádiz and 55 miles northwest of Gibraltar, built in the form of an amphitheater on a broad eminence, in the middle of an extensive plain, noted for its agricultural products and cattle rearing, which constitute the chief occupations of the population. A fine Gothic church, a town hall and the ancestral palace of the famous dukes of Medina-Sidonia are the principal buildings. Pop. (1940) 8,361.

MEDINET EL FAYUM, mă-dē'nĭt ăl fā-yōōm' (more properly EL FAIYÛM, or El FAYUM), town, Egypt, capital of the province of Faiyûm, on the Bahr-Yusef, 70 miles southwest of Cairo. It contains a fine bazar and a mosque. It has an extensive trade in grain, woolens and roses. Woolens are manufactured. Pop. (1947) 72,465.

MEDITATIONS POETIQUES and **NOUVELLES MEDITATIONS POETIQUES.** The *Méditations* (1820) and *Nouvelles Méditations* (1823) of Lamartine should be counted rather as heralds of the Romantic School of French poetry than as products of it. The former, its author's first publication—he was then 30—appeared five years after Waterloo. Its sentimentalized melancholy voiced so admirably the temper of that period of political reaction and moral exhaustion that it achieved a success in its day hardly paralleled. Its appeal was to the cultured only, but 40,000 copies of the *Méditations* were sold in four months. The modern reader must strive to realize the temper of 1820 if he would comprehend how these rather thin and always superficial reflections on the relations of man to "Nature"—a creation of the poet's morbidity, with little relation to reality—rather than to his fellowmen, found admiration so ardent, that successive volumes of verses, in his own phrase, "fell from my pen like drops of evening dew." "The soul of the poet," he writes in a volume of *Confidences,* "is a running brook which writes its murmurs and sings them, but we write them with human notes and Nature with the notes of God."

The *Méditations* were the work of an army officer, but it was the army of the Restoration, decidedly more responsive to Rousseau's call for a return to nature as it was also to Chateaubriand's for a return to religious emotionalism than it was to any summons to action. When that mood passed and France recovered the energy that showed itself in politics by the Revolution of 1830 and in literature by the Romantic School, the *Méditations* soon came to be little read, though still conventionally admired. Unquestionably, however, they were the most complete literary reflection of the sentiments and aspirations, the self-deceptions and illusions of the generation of 1820. This gives them a lasting value, greater than any merit of content or form.

Lamartine's verses preserve much of the

verbal mannerisms of the earlier period. They are harmonious, refined, delicate, graceful, sincere, spontaneous, "the indolent pleasure of a too-richly gifted mind." On the other side they are conventional in expression, monotonous in feeling, elusive in development. The themes are throughout those of the true lyric — nature, love, death. The essence of all Lamartine's voluminous poetic effusion can be seen in its full potency in some of the very earliest of the 'Méditations,' for instance, in The Lake (Le Lac), accounted by some to be Lamartine's best poem, in Loneliness (L'Isolement), and in the vague pantheistic melancholy of Prayer (La Prière). In the 'Nouvelles Méditations' the poet's congenial marriage is reflected in the happier vein of the Love Song (Chant d'Amour), Wisdom (La Sagesse), Ischia and The Preludes (Les Préludes), but the poet soon resumes the melancholy pose. The Ode on Bonaparte in this collection goes deeper and rises higher than is usual in Lamartine; as indeed there is unwonted grace in Ischia and force in The Crucifix. Never so popular as the earlier book, 'Nouvelles Méditations' are preferred by many critics, and Brunetière even pronounced them "at once the noblest and the most *voluptueux* in French poetry." It is juster to say, with Lanson, that if, and so far as, poetry is essentially sentiment, disengaged from the ideas and facts that produce or accompany sentiment, the 'Méditations' are great poetry and Lamartine is among the most poetic of poets. Consult 'Life of Lamartine' by H. R. Whitehouse (New York 1919).

BENJAMIN W. WELLS,
Author of 'Modern French Literature.'

MEDITATIONS OF MARCUS AURELIUS, The. There is probably no more romantic story of a book in the history of literature than that of the volume known as the 'Meditations of Marcus Aurelius.' It is merely the commonplace book or diary of a Roman emperor (121–180 A.D.), who at the end of a very busy and troublous reign, just when worries were thickest, jotted down all the serious thoughts that came to him with regard to the meaning of life and the way it should be lived. He called his little book simply "To Himself." It was probably meant only for his own perusal when he was in meditative mood. He so loved the Greek Stoic philosophers whose writings had been his inspiration and consolation that he wrote in Greek. It is not good Greek any more than the 'Imitation of Christ' is good Latin. He paid little attention to the style of it, and yet Headmaster Rendall of Charterhouse in his Introduction to the 'Meditations' does not hesitate to say that "in the whole range of Greek literature, no work (excepting the New Testament) has wider vogue and currency than these untutored meditations of the imperial moralist."

The book created a *furore* in the Renaissance when it was first edited and printed, but it has never ceased to be the favorite reading of thoughtful scholars. John Stuart Mill declared the 'Meditations' as "almost equal in ethical elevation to the Sermon on the Mount." Matthew Arnold went so far as to say that "Marcus Aurelius remains the especial friend and comforter of all clearheaded and scrupulous, yet pure hearted and upward striving men in those ages most especially that walk by sight, not by faith, but yet have no open vision." Americans will be interested to know that the 'Meditations' of Marcus Aurelius were with Machiavelli's 'Art of War' the daily study of Capt. John Smith, the Virginia pioneer whose romantic history might seem to indicate some less stern and stoic reading. The Roman emperor's little book has often since been the daily resource or even the boon companion of men of action in the field as well as of statesmen worried over matters of politics, and of scholars with time on their hands.

It has been suggested that perhaps this last of those Spanish Cæsars, under whose rule for 80 years Gibbon thinks that the world was happier than it has ever been before or since, had the idea while he was jotting down these scattered thoughts on life that some time or other they might be of service to his son Commodus. If that were so, the book might serve as the contrast to Chesterfield's letters. The modern English nobleman wrote an epitome of worldliness; the ancient emperor a manual of otherworldliness. But if Marcus Aurelius wrote for the eye for his son, he was sadly disappointed, for Commodus was probably one of the worst rulers of history. For his weak selfishness no advice would have availed.

The 12 books treat of: I, The debts that he owes for all that has come to him in life — (here are tributes to his grandfather — his father died when he was very young — to his wife "so docile, so affectionate, so simple," and to many dear friends); II, On doing what you do; III, That to obey God is liberty; IV, That there is no such thing as chance; V, On the real goods of life; VI, That the inner life is all that counts; VII, On repressing impulse and finding self-content; VIII, On equanimity; IX, Fate leads the willing man, but drags the unwilling; X, Look around you, look behind you, look ahead of you; XI, Unselfishness; XII, (In conclusion) "Depart then satisfied for he who also releases thee is satisfied."

When the Emperor Julian whom the modern world knows as the Apostate would sum up the life of Marcus Aurelius in a single phrase he gave an excerpt from a dialogue supposed to take place not long before his predecessor's death: "Then Hermes, looking at Marcus, said, 'And to you, Verus [Marcus' family name], what seemed the noblest end of life?' Quietly and gravely he replied, 'The imitation of God.' "

Consult Watson, 'Life of Marcus Aurelius' (New York 1884); 'Marcus Aurelius,' in Matthew Arnold's 'Essays in Criticism'; Rendall, 'Marcus Aurelius Antoninus' (London 1901); Long, 'The Meditations of the Emperor Marcus Aurelius Antoninus' (London 1862); Canon Farrar, 'Marcus Aurelius,' in 'Seekers After God.'

JAMES J. WALSH.

MEDITERRANEAN (med"ĭ-tĕ-rā'nē-an) **SEA,** the great inland sea between the continents of Europe, Africa and Asia, the remnant — according to Professor Suess — "of a great ocean which at an early geological epoch, before the formation of the Atlantic, encircled half the globe along a line of latitude." From its eastern extremity in Syria to the Strait of Gibraltar it is about 2,300 miles long; its maximum width from Venice to the Bay of Sidra

is 1,200 miles; its average width 300 miles. Its area is variously estimated as from 815,000 square miles to 1,145,000 square miles. The shores of Europe are on the north and northwest, those of Africa on the south and those of Asia on the east. The Mediterranean is connected with the Atlantic by the Strait of Gilbraltar, and on the northeast with the Black Sea through the Dardanelles, Sea of Marmora and the Bosphorus, which form a continuous waterway. It is irregular in shape and by the projection of the south part of Italy, and of Cape Bon in Africa and the interposition of the island of Sicily, is divided, near its centre, into two distinct portions, an east and a west. In addition to these, the other important subdivisions are the Tyrrhenian or Tuscan Sea, between the west coast of Italy and the islands of Sardinia and Corsica; the Adriatic Sea or Gulf of Venice, between the east coast of Italy and the west coast of Yugoslavia and Albania; the Ionian Sea, between the west coasts of Albania and Greece, and the south part of Italy and the island of Sicily; the Aegean Sea or Archipelago, between Greece on the west and Turkey in Asia on the east; and the Levant, which is usually understood to include the whole sea east of the island of Crete. The largest gulfs are, on the shores of Europe, those of Lion or Lyons, Genoa, Taranto, Lepanto, Koron, Kolokythia and Salonica; on the shores of Asia, Adrymiti, Smyrna, Adalia, and Skanderoon; and on the shores of Africa, Sidra and Cabes. The largest and most important islands are Sicily, Sardinia, Corsica and the Balearic Isles, in the west division; and Cyprus, Rhodes, Crete, the Ionian Isles and Malta, in the east division. The principal rivers which discharge themselves into the Mediterranean are the Ebro, Rhone, Po and Nile; but its communication with the Black Sea entitles it to claim it as part of its basin, and, consequently, also the great rivers Don, Dnieper, Dniester and Danube. Between Cape Bon and the Sicilian coast, where the sea is shallowest, the depth varies from 30 to 250 fathoms; but in almost all other places, particularly at a distance from the shores and islands, the depth is very much greater, the maximum depth in the eastern division being 2,150 fathoms, in the western division, 2,040 fathoms. The mean depth is practically equal in the east and west divisions, about 883 fathoms. However, half the area is less than 500 fathoms deep. The depth temperatures are very much warmer than in the Atlantic. Owing to the very narrow channel which connects the Mediterranean with the main ocean, there is very little tide; though in some places, as in the Ionian Sea, the Adriatic, on parts of the African coast, etc., a rise of more than six feet sometimes occurs. The prevailing winds are the southeast and southwest in spring, and the northeast and northwest during the rest of the year. They often rise suddenly and with great violence. The most remarkable are the historic Euroclydon or Levanter, mentioned in Acts 27:14, a northeast wind of dangerous whirlwind characteristics; the Bora in the Adriatic; the Etesian and Tramantona in the Aegean; and the burning sirocco from the African desert. The Mediterranean abounds with fish, some 400 species having been noted, and also furnishes the finest coral and sponge. The evidences of volcanic action along its shores are present in the active volcanoes of Vesuvius, Etna and Stromboli (qq.v.). Consult Cook, J., *The Mediterranean and Its Borderlands* (Philadelphia 1910).

MEDITERRANEAN SUBREGION, a subdivision of the Palaearctic region, embracing the basin of the Mediterranean and the plains of Syria. See Zoogeography.

MEDIUM, THE, a two-act opera by Gian-Carlo Menotti (q.v.); libretto by the composer. First produced at the Brander Matthews Hall of Columbia University, New York, May 8, 1946. In the following February it was given three performances by the Ballet Theatre at The Heckscher Theatre in New York, together with the premiere performances of Menotti's *The Telephone* (q.v.). Commencing May 1, 1947 the two operas were produced under commercial sponsorship at The Barrymore Theatre in New York, and continued for several months consecutive run of nightly performances.

Both acts take place in Madame Flora's parlor, in contemporary times. Madame Flora is a fraudulent medium who uses her daughter Monica, and the deaf-mute Toby, as confederates. Toby is deeply in love with Monica. In the midst of a séance Madame Flora feels a cold hand about her throat. She is so frightened that she exposes her tricks to her clients, Mr. and Mrs. Gobineau and Mrs. Nolan. The clients refuse to be undeceived, but Madame Flora cannot believe that the hand on her throat was a supernatural phenomenon. She insists that Toby was trying to kill her. She threatens the boy and beats him, and in spite of Monica's pleadings, turns him out of the house. Madame Flora starts drinking and becomes so drunk that she sinks into a stupor. Toby returns, trying to find Monica. Madame Flora revives and Toby hides in the cabinet. In a panic Madame Flora takes her revolver and shoots at the curtains of her cabinet. Toby's body falls to the floor.

MEDJIDIEH. See Orders and Decorations—*Turkish.*

MEDLAR, a small tree (*Mespilus germanica*) of the apple family. Although a native of southern Europe, it is also grown in America. In central New York it is hardy and produces well with no special care. The top-shaped fruit, which is about the size of a small pear, is used for preserves.

MEDOC, mâ-dŏk', a wine which derives its name from a district of France, in the ancient province of Gascony. It is dry, still and delicate, resembling Bordeaux wines, which territory is immediately south of Medoc.

MEDULLA OBLONGATA, the brain-stem, or that part of the nervous system that lies between the *pons,* or *pons Varolii,* at the upper end, and the spinal cord proper, with which it is continuous, at its lower end. It is a very old part of the nervous system, judged from the standpoint of evolution, and in it are located the important centers of most of the cranial nerves, including the centers that govern the nerves of the heart and of respiration. It

is a triangular cone-like portion of the nerve-axis, about an inch in length and one-half to three-quarters of an inch thick, being tubular below and flattened above. Below, it closely resembles the cervical cord in its internal construction, but above great changes take place to accommodate important new structures. One of the most conspicuous features of the medulla consists in a triangular enlargement of the central canal of the cerebro-spinal axis, constituting what is known as the fourth ventricle. The lower seven cranial nerves have their apparent origin in the medulla, and the first spinal nerve also originates in the medulla proper. The internal anatomy of the medulla is complicated. At the lower end the chief motor tracts, the pyramidal tracts that come from the motor area (q.v.) in the brain cross one another to pass down on opposite sides of the spinal cord. It is because of this decussation that a hemorrhage of the brain of the right side causes a paralysis of the muscles of the left side of the body, and *vice versa.* Just above the decussation of the pyramids the end-stations (nuclei) of the two chief sensory tracts of the body are located. It is into these nuclei — the gracilis and the cuneatus — that all of the sense-impressions from the body below the head are collected, to be passed to higher cerebral centres through the lemniscus or sensory fillet. The chief gray masses in this part of the brain are the nuclei of the cranial nerves referred to, and of the olives, two structures of undetermined function. The best description of the oblongata at present is that of the model of the medulla and pons by Dr. Florence Sabin, which is figured in Barker's 'Nervous System.' Consult also Buck, 'Reference Handbook of the Medical Sciences,' article "Brain," and Johns Hopkins Hospital Reports, Welch Memorial Volume. See BRAIN.

MEDUM, Egypt, village on the Nile, 40 miles south of Cairo, near the Pyramid of Snefru. See PYRAMID.

MEDUSA, mẹ-doo'sạ. See GORGO.

MEDUSA, a disk-bearing jellyfish (q.v.).

MEDWAY, England, a river which rises in the county of Sussex and flows northeast in a winding course across Kent, past Tunbridge and Maidstone, to Rochester and Chatham. Below Chatham it spreads out into a broad tidal estuary, in which are several islets, and joins the Thames at Sheerness. It is 70 miles long and is navigable to Penshurst, 20 miles above Chatham.

MEEHAN, mē'ạn, **Thomas,** American botanist: b. Potter's Bar, near London, England, 21 March 1826; d. Philadelphia, 19 Nov. 1901. From his father, a gardener, he learned facts of natural history when a child; at eight made and recorded an original discovery in herpetology; taught himself from books read at night after daily tasks; at 12 began to publish scientific papers; soon after produced the first hybrid fuchsia; and was nominated to membership in the Royal Wernerian Society. For two years he held a position at Kew Gardens. In 1848 he came to America and took charge of Bartram's Gardens in Philadelphia. In 1854 he established the Germantown Nurseries, which he conducted until the end of his life. For 30 years (1859-89) he edited the *Gardeners' Monthly,* and contributed papers to many other periodicals and to scientific societies. For 23 years he was senior vice-president of the Philadelphia Academy of Natural Sciences, in whose proceedings were published his important 'Contributions to the Life History of Plants.' In 1875 he was elected a fellow of the American Academy for the Advancement of Science, before which, among other noteworthy papers, he read 'A Contribution to the Doctrine of Evolution and the Theory of Natural Selection,' which showed him as a coworker with Darwin and other evolutionary scientists, in whose field he also was a discoverer. From the creation of the office until his death he served as State botanist of Pennsylvania, at one time was a member of the board of visitors of Harvard, and was one of the American editors of the 'Encyclopædia Britannica.' His travels and researches extended throughout the country, including Alaska. In 1878 he began the publication of 'Native Flowers and Ferns of the United States,' an illustrated serial covering a wide field of floral distribution, the main features of which he continued in *Meehan's Monthly,* founded in 1891. Many learned societies abroad enrolled him, and he held intimate relations with nearly all the leading scientists of his time. Among his closest friends was the Comte de Paris, a devotee of plant-study. Meehan was the third American to receive the Veitch medal, awarded to him for "distinguished services in botany and horticulture." Apart from scientific work he devoted himself to public labors; was a member of the Philadelphia common councils from 1882 until his death; during the same period served on the local school board; in both capacities introduced many reforms; and chiefly through his efforts nearly 30 small parks were added to the city. A work of permanent value is his 'American Hand-book of Ornamental Trees' (1853).

MEEK, mēk, **Alexander Beaufort,** American jurist: b. Columbia, S. C., 17 July 1814; d. Columbus, Miss., 30 Nov. 1865. He was graduated from the University of Alabama in 1833 and admitted to the bar two years after. He served in the Seminole War 1836; was attorney-general of Alabama 1836; judge of Tuscaloosa County 1842-44; and member of the legislature in 1853. While there he established the free-school system of Alabama. In addition to a legal digest (1842) he wrote: 'The Red Eagle' (1855); 'Songs and Poems of the South' (1857); 'Romantic Passages in Southwestern History' (1857), etc. His best-known poem is 'The Charge at Balaklava.'

MEEK, Fielding Bradford, American palæontologist: b. Madison, Ind., 10 Dec. 1817; d. Washington, D. C., 28 Dec. 1876. His educational advantages were limited, but his interest in natural history made study imperative to him, and in 1848 he became assistant to David D. Owen in a geological survey of Iowa, Minnesota and Wisconsin. He assisted James Hall at Albany in 1852-58, spending several summers in a geological survey of Missouri and Nebraska, and in 1858 went to Washington, where he devoted the remainder of his life to palæontologic investigations under the government. He was elected in 1870 to the National Academy of Sciences, and was a member of

other scientific organizations. Among his writings are 'Check List of the Invertebrate Fossils of North America' (1864); 'Report on Invertebrate Cretaceous and Tertiary Fossils' (1876), etc. For a complete list of his works, see bibliography published by the Smithsonian Institution.

MEEKER, Royal, American statistician: b. Silver Lake, Susquehanna County, Pa., 23 Feb. 1873. In 1898 he was graduated at Iowa State College and in 1906 took the degree of D.Ph. at Columbia University. He also studied at Leipzig. In 1904–05 he was professor of history, politics and economics at Ursinus College, Collegeville, Pa. In 1905 he became preceptor at Princeton and from 1908 to 1913 was assistant professor of political economy there. On 12 Aug. 1913 Dr. Meeker was appointed commissioner of labor statistics by President Wilson. In 1926–27 he was professor of economics, Carleton College, Minn. He published 'History and Theory of Shipping Subsidies' (1905).

MEEKINS, Lynn Roby, American journalist: b. Salem, Md., 14 Nov. 1862; d. 8 Nov. 1933. He was graduated from Western Maryland College, Westminster, Md., in 1882, and devoted himself to journalism. He was literary editor of the Baltimore *American* 1882–99; managing editor, *Saturday Evening Post,* 1899–1901; editor, Baltimore *Herald,* 1903–06; editor, Baltimore *Star,* 1908–11; on editorial staffs *News* and *American,* Baltimore after 1920. He published 'Robb's Island Wreck'; 'Adam Rush,' etc.

MEERANE, Saxony, town, 10 miles north of Zwickau and 36 miles south of Leipzig. It contains a mediæval church. Meerane is one of the largest textile-producing centres of the state, turning out vast quantities of woolen and mixed cloths. It has also extensive dyeing establishments, machine works, tanneries, boiler works, motor factories, button, paper box and cement works. The town has a Realschule, a textile school and a school of commerce. Pop. 24,094. Consult Leopold, 'Chronik und Beschreibung der Fabrik-und Handelstadt Meerane' (1863).

MEERKAT. See SURICATE.

MEERSCHAUM (Sepiolite), mēr'shâm or -shum, a name given to one of the silicates of magnesium; it is a mineral of a whitish or creamy color, and received its name from its appearance and the position in which it is sometimes found suggesting that it was petrified foam of the sea. It is obtained from various places, but the best quality comes from Asia Minor, rich deposits of it existing about 20 miles southeast of Eskichehir, at a place called Sepetdje. Here are some 20,000 pits in a space of six miles, of which only 150 are worked, all the others being exhausted. It is said that these mines were opened 1,000 years ago, which is not incredible, as it is well known that magnesia was formerly used for many purposes, other than the fabrication of pipes; moreover, fuller's earth was once worked on a vast scale by the ancients. The meerschaum mines are worked by some 500 miners, who live in the surrounding villages. At Gheikli, in the neighborhood of Sepetdje, there are 3,000 pits, of which only 100 are worked, giving employment to 400 miners. The mineral is mined in blocks, which are taken to Eskichehir, where the blocks are cleaned, the operation consisting of scraping and cutting the blocks with a sharp instrument or knife, the meerschaum being still soft and easily cut into any shape or form. Over 1,100 persons are occupied in cleaning and shaping these blocks, which, after being thoroughly cleaned, are separated into four classes, according to size and quality. These blocks being ready for sale, a bargain is struck between the pipe manufacturers and the commission agents and merchants at Eskichehir, of whom there are about a dozen. The latter then pack the blocks of these four classes with very great care into boxes of equal size, each block being wrapped in cotton to avoid any friction or shock between the pieces. The actual annual output of these mines varies from 120 to 150 tons. It is soft when dug up, but becomes hard when dry. Most of it is sent to Vienna, where it is chiefly made into tobacco-pipes, many of them highly artistic. Similar pipes are also made in Paris, London and elsewhere.

MEERUT, India, the capital of the district and division of the same name, in the United Provinces, situated 40 miles northeast of Delhi on the Northwestern Railway. The city is irregularly built, with narrow, filthy streets. It contains several mosques, a fine town hall, a college, normal school and church schools. At Meerut is one of the largest cantonments in India. Flour and soap are the principal manufactures. The first outbreak of the Indian Mutiny of 1857 occurred at Meerut. The city has a good water supply and an excellent drainage system. Pop. 123,000.

MEES, Arthur, American musical director: b. Columbus, Ohio, 13 Feb. 1850; d. New York City, 26 April 1923. He was graduated from Concordia College, Fort Wayne, Ind., and studied music in Berlin. He was assistant director, and later director, of some of the leading operas and musical associations, and published, in addition to his annotated programs for the New York Philharmonic Society and the Chicago Orchestra, 'Chorus and Choral Music.'

MEGACLES. The most illustrious Greek of this name was the head of the family of the Alcmæonidæ at Athens in the time of Solon. After twice expelling Pisistratus, who in 560 B.C., had made himself «Tyrant» of Athens, he was himself exiled by the latter together with all his family.

MEGALENSIA, or MEGALESIA, an annual festival at Rome (4–10 April) in connection with the foreign cult of Cybele, the *Magna Mater* or Great Mother of the Gods, celebrated by a procession of her eunuch-priests, by circensian and theatrical shows, and at the close a carnival.

MEGALITHIC MONUMENTS. See DOLMEN; MENHIRS; STONES, STANDING; STONE CIRCLES.

MEGALONYX. See GROUND-SLOTHS.

MEGALOPOLIS, mĕg-ą-lŏp'ō-lĭs, or **SINANON,** Greece, a ruined city on the ancient Helisson, in the nomarchy of Gortynia, 5 miles north of Leondari. It was founded 370 B.C. by Epaminondas (q.v.) as the federal capital of Arcadia and was a magnificent walled city, five and one-half miles in circumference; it was frequently but unsuccessfully attacked by the

Spartans. In 222 B.C. it was captured and partially destroyed by Cleomenes III. From 1890–93 the British School at Athens excavated the site and revealed the Precinct of Zeus Soter, the Agora, the Stoa of Philip and the Stoa of Myropolis, etc.

MEGALOSAURUS, mĕg″ą-lō-sâ′rús, a genus of huge carnivorous dinosaurs of the group *Theropoda.* Their remains occur frequently in the European oölitic rocks. The extreme length was about 50 feet. They were covered with scales and built like lizards, but with proportionally longer, heavier legs. See DINOSAURIA.

MEGANTIC, Canada, town and county seat of Frontenac County, Quebec, on Lake Megantic, the Chaudiere River and the Canadian Pacific Railway, 50 miles east by north of Sherbrooke. It is the seat of a business college and of a convent. The leading industry is the manufacture of pulp. Pop. 5,000.

MEGAPHONE (a Greek word meaning «great sound»), an instrument magnifying the sound of the voice many times, so that one can be heard at a considerable distance. In its simplest form it is a cone-shaped trumpet, and the speaker shouts into the small end, the instrument directing the sound waves wherever it is aimed. This form is used by announcers at base ball games, etc. The form invented by Thomas A. Edison consists of two large funnel-shaped receivers in which the waves of sound are collected and concentrated and carried by means o. flexible tubes held to the ears of the person using the instrument. In the instrument called telephone-megaphone, the mouthpiece of the telephone is connected with four transmitters which multiply the usual telephone sound of the voice by four, and it is sent by wire, so increased, into the megaphone, which sends it forth into space with sufficient intensity to carry it with perfect distinctness throughout a large church or hall. One form of megaphone is largely used by deaf persons.

MEGAPODES, a general name for the brush-turkeys or mound-birds of Australia constituting the gallinaceous family *Megapodiidæ,* so named in reference to the disproportionately large size of the feet; and remarkable for their breeding habits. The family, although mainly Australian, is represented in many of the South Sea Islands and in the Philippines, replacing the pheasants, which are absent from that region. There are 7 genera and 20 or more species, mostly with restricted individual ranges, and varying in size from that of a turkey to that of a large pigeon, the sexes being always alike in plumage. The general colors are browns and yellows with the naked wattled parts brightly colored. They have a short, strong bill; the head and neck almost naked and wattled; the wings short and round, the tail large; the legs and feet large, strong and provided with great claws. Megapodes are terrestrial birds found in hill-valleys, among thickets or along river and sea beaches. They run well, but if hard pressed will take to trees where they hop about awkwardly; their flight is heavy, but may be long sustained. Hoarse, chuckling, cackling or mewing cries express the utterances of the different species, which are often heard at night. The food consists of fallen fruit, seeds, berries, worms, snails, insects and even small crabs. The flesh is dark-colored and not good, though palatable to the Australian aborigines.

One of the best known species is the brush-turkey or mound-turkey (*Catheturus lathami*), also known as the wattled talegalla and the New Holland vulture, the latter name being given to it on account of its yellow, naked head and neck, covered in part with fleshy wattles. It is rather common in New South Wales, inhabiting the most thickly wooded parts. It is a large bird, about the size of a turkey, with blackish-brown plumage. It is shy, and when pursued, endeavors to escape by running through the thickest brush, or by leaping to the lowest branches of a tree, and thus avoids the dingoes or native dogs, which, however, often hunt it down on open ground. It is easy game to the sportsman, who finds it roosting under shelter of the branches of trees during the heat of the day, and although several of a flock are shot, the rest keep their place undisturbed. They are generally seen in small flocks, and make their nests together, the females heaping up, by means of their feet, mounds of several cartloads of earth and decayed leaves, which are used from year to year, new materials being added every year. The eggs are separately buried, often by several females, within the mass, where they are hatched by the heat of the fermenting mound. The parent birds partially uncover them during the day. Nearly a bushel of eggs may sometimes be found in a single heap. The male bird pays great attention to the young after they are hatched, covering them up partially in the mound at night for warmth. The flesh of the talegalla is excellent, and the eggs are also very delicate and eagerly sought after. Two other species occur in New Guinea.

South and West Australia have another familiar megapode in the mallee-hen or «native pheasant» (*Lipoa occellata*)—a large gray-brown bird with eye-like markings on the wings and back, and the naked neck and wattles blue; its mounds are comparatively small and often made individually. A bird often confounded with this in books because of similarity of name is the maleo (*Megacepalon maleo*) of North Celebes, which has the singular habit of making a general migration in the breeding season to the sea-beach, where small groups of females dig large holes in the sand just above high-water mark, and day by day bury eggs there until the quota of each is laid; these gradually hatch under the influence of the hot sand. The largest genus is *Megapodius,* whose 15 species are scattered over all the island region between Samoa, the Philippines and the Micobars, each group having a distinct species. The most widely distributed and best known is *M. tumulus,* the common mound-bird or scrub-turkey of Northern Australia and the Papuan archipelago, which fashions mounds 10 or 11 feet high in the densest woods, continues to use them year after year, and lays pale, coffee-colored, thin-shelled eggs in straight burrows penetrating the mound. In some islands the eggs of these birds are an important food resource. The young are well fledged when they emerge from the egg and scramble out of the mound, but are attended to by their parents for some time. Consult Newton, 'Dictionary of

Birds' (1869); 'Proceedings,' Zoological Society of London, 1876, 1888, etc., and works on the ornithology of Australia and Oceanica.

MEGAPOLENSIS, Joannes, Dutch Protestant missionary to the North American Indians: b. Koedyck, Holland, 1603; d. New York, 24 Jan. 1670. His family name, van Mekelenburg, he Hellenized to Megapolensis. In 1642 Van Rensselaer, the first Patroon, brought him to New York from Holland, and he soon learned the Mohawk tongue and preached successfully among the Indians near Albany, several years before John Eliot's mission or any other Protestant preaching to the Indians. From 1649 until his death he was pastor of the Dutch church in New York, where he showed little tolerance to Lutherans and Independents. He advised peaceable surrender to the English in 1664. His account of the Mohawks is published in the third volume of the New York Historical Society's 'Collections' (1870).

MEGARA, Greece, the capital of ancient Megaris (q.v.), between Attica and Corinth; also a modern town in the eparchy of Megaris, of 9,500 population.

MEGARIAN SCHOOL OF PHILOSOPHY, a Greek school of philosophy based on and developed from a part of the Socratic system. Euclid of Megara was the first to give definite form to its teaching. Eubulius was also a prominent member of this school, which confined itself mainly to dialectic methods, and sought to unite the Socratic ethical principle and the Eleatic theory of the One, to whom only true being might be attributed.

MEGARIS, mĕg'a-rĭs, Greece, the name of an ancient state or small district bounded north by Bœotia, east by Attica, south by the Saronic Gulf and the territory of Corinth, west by the Corinthian territory and the Corinthian Gulf; area, about 143 square miles. It is a mountainous country, the only plain being that on which the capital was situated. Mount Cithæron was on the north boundary, separating it from Bœotia. The people were traders and sold their textiles over a large area. The only important town was Megara, situated a mile from the sea, opposite the island of Salamis. It contained a Pelasgian citadel, called Caria, on a hill northwest of the city, with a temple to Demeter called Megaron, from which the name of the town is supposed to be derived. It had flourishing colonies at an early period, and its navy was so powerful that it was only after a long struggle with it that Athens obtained possession of Salamis. It afterward became annexed to Attica, of which Megaris formed one of the four ancient divisions. It was successively conquered by the Dorians and the Corinthians, but afterward asserted its independence, and became wealthy and powerful.

MEGASTHENES, a Greek historian, who about the year 300 B.C., as ambassador of King Seleucus Nicator at the court of the Indian king Sandracottos, gathered the material for a geographical and historical account of India that, reaching us in the form of fragments and worked over in Strabo, Diodorus and Arrian, is our chief source of knowledge of that country in antiquity. There is an edition of the fragments by E. A. Schwanbeck (Bonn 1846); also a translation by McCrindle, 'Ancient India as Described by Megasthenes and Arrian' (Calcutta 1877).

MEGATHERIUM, a gigantic fossil ground-sloth, the largest known edentate, representing the family *Megatheriidæ,* and especially the species *Megatherium americanum,* whose remains are found plentifully in the Pleistocene strata of Argentina and Patagonia. These early edentates were so generalized, that, as compared with modern forms, they exhibit the head and teeth of a sloth, associated with the vertebræ, limbs and tail of the ant-eater. Some of them attain a gigantic size, at least as large as an elephant, but with shorter limbs and a bigger tail, and the latest species are the most bulky. *Megatherium,* according to Woodward, seems to have been entirely destitute of dermal armor. The only one of its allies in which bony plates have been discovered is *Mylodon,* and they are very small and not fused together. The pelvis and hind limbs are heavily formed, showing that the animal was in the habit of standing on them, steadied by the powerful tail, like a kangaroo. They fed on the branches of trees. The mylodons were somewhat smaller than the megatheria, with a skull and teeth more like those of the modern sloths, and the three inner digits of the forefoot bear claws, about equal in size, instead of the huge middle-finger claw of the Megatherium. In both animals the hind foot lacks digit I, but II and III bear claws. The typical species of mylodon (*M. harlani*) was about as large and of much the same form as a rhinoceros, and inhabited the southwestern United States, while various other species lived in South America. The long-headed South American genera, *Scelidotherium* and *Megalonyx,* are other forms of the same family. See GROUND-SLOTHS. Consult the palæontological writings of Leidy, Lydekker and Woodward; also Scott, G. B., 'History of Land Mammals' (1913).

MEGIDDO, an important fortress city of ancient Canaan. Thothmes III captured it in the 23d year of his reign, and took therefrom magnificent spoils. The city is mentioned several times in the Tel-el-Amarna correspondence. Though nominally in the territory of Manasseh (Jos. xvii, 12, 13; Judg. i, 27, 28) it remained in possession of the Canaanites. Near the «waters of Megiddo» Barak and Deborah defeated the Canaanites under Sisera (Judges v, 19–21). Solomon restored the fortifications (1 Kings ix, 15) and Ahaziah is said to have died there (2 Kings ix, 27). Finally it was at Armageddon (*Har-Magedon,* mountains of Megiddo) that the great conflict of Revelations xvi, 16, was to take place. The site of Megiddo may now be considered as proved to be Tel-el-Mutesellim, a great mound four miles northwest of Tel Taanach. It was evidently of great strategic importance since it commanded the pass from the Plains of Sharon to the Plain of Esdraelon, which in all the centuries from Thothmes III to Allenby in 1917–18 has been the route of armies. Fortifications preceding 2000 B.C. have been uncovered on the site, together with the remains of several cities which rose here successively and vanished. Here too was found the seal of Shama, servant of Jeroboam (II?). In Roman times the place was a fortified post — the *Legio* of

Eusebius, the modern *el Lejjun*. Consult Schumacher, 'Tell el Mutesellim: Bericht über die 1903 bis 1905 veranstalteten Ausgrabungen I' (Leipzig 1908).

MEGNA, mĕg'nạ, or **MEGHNA,** India, the estuarine outlet of the Ganges and Brahmaputra (qq.v.), in Bengal. There are four principal mouths, producing three islands. The tidal bore is characterized by its velocity, which endangers navigation, advancing at the rate of 15 miles an hour, and frequently attaining a height of nearly 20 feet. As the bottom is loose sand; it shifts continually, making navigation difficult.

MEGRIM. See MIGRAINE.

MEHEMET (mā'hĕ-met), or **MOHAMMED** (mō-ham'ĕd), **ALI,** viceroy of Egypt: b. Kavala, Macedonia, 1769; d. Cairo, 2 Aug. 1849. An orphan, he was brought up by a janizary captain, governor of Kavala, who married him to a kinswoman and made him a militia officer. When the French invaded Egypt he was sent there, rose rapidly, became the confidant of Koshrew, pasha of Egypt, and, by treachery both to the pashas and the Mamelukes and by a liberal use of his wealth, in July 1805 became pasha of Cairo, whence his power quickly spread over the rest of Egypt. His utterly unscrupulous policy was shown by his massacre of nearly 1,700 Mamelukes in 1811. He extended the limits of Egypt by wars on the Arabian Wahabees, by the possession of Nubia and Kordofan, and by the treacherous conquest of Syria, in which he aimed at independence of the Porte. This first break with Turkey was settled by the Powers; and in 1839 the Sultan was forced to call on the Powers to help him turn Mehemet out of Syria: by the treaty then concluded he surrendered Syria, Candia and Hejaz; but was made hereditary pasha. His internal administration was vigorous; both agriculture and manufactures flourished, thanks to French capital solicited by Mehemet, who also introduced European methods into his army, and established a system of education. He was insane during the latter part of his life, and was succeeded by his grandson; his son, who took his place as regent in September 1848, died in November 1848.

MEHMET, Turkish form for MOHAMMED.

MEHRING, Franz, German historian, critic and socialist philosopher: b. Schlawe, Pomerania, 27 Feb. 1846; d. Berlin, 29 Jan. 1919. He was of middle-class Pomeranian origin, but became interested early in life in the struggles of the poor. His life is an interesting example of the career of a political thinker who passes out of the organizations of his own class and into those of the lower classes, by natural sympathy, although in Mehring's case this process took a long time. He attended the University of Berlin, where he obtained the Ph.D. degree, simultaneously working for a democratic newspaper, *Zukunft,* under the direction of Johann Jacoby and Dr. Guido Weiss. After this paper was suppressed (1871), he became a member of the staff of *Die Wage,* a weekly edited by Dr. Weiss. In 1873 appeared Mehring's first socialistic pamphlet, "Herr von Treitschke, der Sozialistentöter, und die Enziele des Liberalismus," which, as its title indicates, is an attack upon Treitschke (q.v.). When the two chief socialistic bodies in Germany united at Gotha in 1875, Mehring was sympathetic to the new party but did not become a member, and a rather personal controversy which he had with Leopold Sonnemann, editor of the *Frankfurter Zeitung,* for which Mehring had been Berlin correspondent, removed him more and more from the activities of the Social-Democratic party. From 1877 to 1882, Mehring was unfavorably disposed toward the leaders of the party, and in his 'Geschichte der deutschen Sozialdemokratie,' which he began writing in those years, he made many attacks upon them, for which he was seriously taken to task at the Dresden Party Congress. He defended himself in a little book 'Meine Rechtfertigung' ('My Justification'), in which he asks forgiveness for having been so foolish as to believe that the monarchic régime might develop into an honest democratic republic, which idea, he explains, has been completely corrected by the anti-socialistic laws as administered by the Prussian government. Yet Mehring still hoped that it might be possible to found a bourgeois democratic party in Germany, in which work, which was foredoomed to failure, he was associated with Lenzmann (1884). He was editor-in-chief of the *Berliner Volkszeitung* (1885–89), but was forced to resign from that paper because of a controversy with Paul Lindau (q.v.), arising out of the latter's maltreatment of the actress Elsa von Schabelski (by a curious coincidence, Paul Lindau's death in January 1919, coincided almost to a day with that of Mehring). Mehring has written profound historical analyses, among which the best are 'Die Lessing-Legende' (1893) and 'Gustavus Adolphus' (1894). As a man of 70 his hostility to the German Imperial government was still unbroken, and together with Rosa Luxemburg and Karl Liebknecht he wrote, in January 1915, a pamphlet attacking the militaristic system that had plunged Europe into war, known as the "Junius" pamphlet. This appeared in Switzerland and was secretly circulated in Germany (English translation: 'The Crisis in the German Social-Democracy,' New York 1918). He spent considerable parts of 1916 and 1917 in jail, under "preventive detention," but had to be released because of his failing health. In January 1918 he was elected a member of the Prussian Landtag, on the socialist ticket, and distinguished himself in that body by his biting comments on the inability of the Prussian military leaders; Mehring had always had a sort of amateur interest in military affairs; a number of his pamphlets deal ably with questions of this kind. Shortly before (September 1918) the final defeat of the German armies (October) on the western front, Mehring predicted that the hope of the militarists in the inability of the United States to land sufficient troops in Europe would be disappointed. His death was due to pneumonia, and coming, as it did, close upon the murder of Liebknecht and Rosa Luxemburg (15 Jan. 1919), it considerably depressed the hopes of the radical element ("The Reds") of the German Social-Democracy. Of the four chief leaders of the so-called "Spartacus" group, three had therefore met death in one month, and only one, Klara Zetkin (q.v.), an old woman, herself seriously ill, was still alive

in April 1919. Consult also *Die Neue Zeit* (1882 et sequitur, Stuttgart); *The Class Struggle* (New York 1917 et sequitur).

JACOB WITTMER HARTMANN.

MÉHUL, Etienne Henri, ā-tē-ĕn ŏn-rē mā-ül, French musical composer: b. Givet (Ardennes), 22 June 1763; d. Paris, 18 Oct. 1817. For some years he substituted the name Nicholas for Henri. He studied at Paris under Gluck; and after the departure of the latter for Vienna, Méhul presented to the Royal Academy of Music the opera of 'Cora and Alonzo,' the representation of which was delayed for six years. He then turned to the Opéra Comique, which gladly received his 'Euphrosine and Coradin' in 1790. His patriotic hymns, 'Chant du Départ,' 'Chant de Victoire,' and 'Chant Retour,' greatly increased his fame. He was chosen a member of the Institute in 1796, of the Academy of Fine Arts in 1816, and a knight of the Legion of Honor in 1802. His chief operatic work is 'Joseph' (1807). His style as a composer is remarkable for dramatic force and coloring. There is a 'Life' by Pougin (1889). His statue was erected in his native town in 1892.

MEIBOMIA, a genus of erect perennial herbs of the pea family, of which about 150 species are natives of warm and temperate America, Africa and Australia. More than 40 species belong to the United States, some of the more familiar of which are called «tick-seeds.»

MEIDERICH, Prussia, town of the Rhine province, 15 miles northeast of Krefeld. It contains several large iron and steel mills, machine shops, brickyards, phosphate works and saw mills. Coal deposits are worked in the vicinity and there is a large cattle trade. Its history as an industrial centre began in 1850. It was annexed to Duisburg in 1905. Pop. 40,000. Consult Graeber, 'Tausendjährige Geschichte von Meiderich' (1893).

MEIER, Edward Daniel, American mechanical engineer: b. Saint Louis, Mo., 1841; d. 1914. In 1858 he was graduated at Washington University and subsequently studied four years at the Royal Polytechnic College at Hanover, Germany. In 1863 he enlisted in the 32d Pennsylvania Volunteers; served later in the artillery and in the engineers and was a cavalry lieutenant at the close of the war. He entered locomotive works at Paterson, N. J., after the war, became superintendent of machinery of the Kansas Pacific Railroad in 1867; chief engineer of the Illinois Coke Company in 1870; and two years later constructing engineer of the Meier Iron Company. He founded the Heine Safety Boiler Company of St. Louis in 1884, of which he was president in 1914. For many years Mr. Meier was president of the American Diesel Engine Company. In 1908–14 he was president of the American Association of Boiler Manufacturers and of the Machinery and Metal Trades Association. In 1911 he was president of the American Society of Mechanical Engineers.

MEIGGS, mĕgz, **Henry,** American contractor: b. Catskill, N. Y., 7 July 1811; d. Lima, Peru, September 1877. He was engaged in the lumber business in New York and other places but met with financial reverses and in 1848 went to California, where he again took to the lumber business and gained an immense fortune. Reverses, however, once more swept away his wealth, leaving him with an indebtedness of more than $1,000,000. He fled with his family to Peru, where he soon embarked upon a series of bridge- and railway-building enterprises which won for him immense wealth and a world-wide fame as a railway contractor. His engineering achievements in South America comprise some of the most daring feats in the history of the profession. The construction of the Callao, Lima and Oroya road, which crosses the Andes, was his crowning achievement.

MEIGHEN, Arthur, Canadian statesman: b. Anderson, Ont., 16 June 1874. He was educated at Toronto University and became a barrister. In 1908 he was elected to the House of Commons and in 1913, was Solicitor-General in the Borden government and Secretary of State and Minister of Mines, 1917. He was premier of Canada in 1920–21, and again in 1926 from July to September.

MEIGS, Charles Delucena, American physician: b. Saint George, Bermuda, 1792; d. 1869. In 1809 he was graduated at the University of Georgia, and in 1817 at the medical college of the University of Pennsylvania. In the same year he established his practice in Philadelphia and became prominent as an obstetrician. He was professor of obstetrics and diseases of women and children at the Jefferson Medical College from 1841 to 1861. He was one of the first editors of the *North American Medical and Surgical Journal,* which he helped to found in 1826. Dr. Meigs published 'The Philadelphia Practice of Midwifery' (1838; 2d ed., 1842); 'Lectures on Some of the Distinctive Characteristics of the Female' (1847); 'Females and their Diseases' (1848; 2d ed. with title 'Woman; Her Diseases and Remedies,' 1851; 3d ed., 1854); 'Remarks on Spasmodic Cholera' (1849); 'Obstetrics' (1849; 3d ed., 1856); 'Observations on Certain Diseases of Children' (1850); 'Treatise on Acute and Chronic Diseases of the Neck of the Uterus' (1854); 'On the Nature, Signs and Treatment of Childbed Fevers' (1854); translations of Hufeland's 'Treatise on the Scrofulous Disease' (1829); Velpeau's 'Elementary Treatise on Midwifery' (1831); Colombat de L'Isère's 'Treatise on the Diseases and Special Hygiene of Females' (1845). Consult Meigs, John F., 'Memoir of Charles D. Meigs' (Philadelphia 1872).

MEIGS, Montgomery, American civil engineer: b. Detroit, Mich., 27 Feb. 1847. He was educated at Harvard and in Germany, and was for several years in the employ of the Northern Pacific Railroad. In 1882–1926 he had charge of the Des Moines Rapids Canal under the government. He is the inventor of a «canvas coffer-dam.» He also constructed the United States dry dock at Keokuk. In 1898 he proposed a new method of improving country roads by using oil with a sprinkler to make a water-tight surface and lay dust, which attracted wide attention and has since been generally adopted. He built and designed many steamboats and steam dredge tenders for the United States. In 1910–13 he was the government local inspecting engineer in the construction of the great lock, dry dock and power developments in the Mississippi at Keokuk, Iowa. Died 9 Dec. 1931.

MEIGS, Montgomery Cunningham, American soldier and engineer: b. Augusta, Ga., May 3, 1816; d. Washington, D.C., Jan. 2, 1892. He was graduated from West Point in 1836, and entering the engineering corps the next year, was engaged in the construction of forts in the Great Lakes region until 1852 when he took charge of building the Potomac Aqueduct and, later, other structures in Washington, including parts of the Capitol. In 1861 he was appointed quartermaster general of the army, which post he held throughout the Civil War.

MEIGS, Return Jonathan, American soldier and pioneer: b. Middletown, Conn., Dec. 17, 1740; d. at the Cherokee agency, Tenn., Jan. 28, 1823. After the Battle of Lexington, he marched a company of men to the American camp at Cambridge. He subsequently accompanied Benedict Arnold's expedition against Quebec where Meigs was taken prisoner. Following his release, he led a brilliant raid on the British at Sag Harbor, Long Island, in 1777. In 1779, he further distinguished himself under Anthony Wayne during the capture of Stony Point, N. Y. In 1788, he emigrated to Marietta, Ohio. In 1801 President Jefferson appointed him a Cherokee agent.

MEIGS, Return Jonathan, American statesman, son of the preceding: b. Middletown, Conn., Nov. 17, 1764; d. Marietta, Ohio, March 29, 1824. He went to Marietta with his father in 1788 and became a prominent lawyer. He was the first chief justice of Ohio (1803–1804); a judge in Louisiana 1805–1806, and in Michigan. He was a senator from Ohio from 1807 until 1810 and governor of that state for the next four years, during which period he was an active supporter of the war measures of 1812–1814. He was postmaster-general of the United States from 1814 until 1823.

MEIGS, William Montgomery, American historian and lawyer: b. Philadelphia, Aug. 12, 1852; d. Dec. 30, 1929. He was admitted to the bar in 1879, but ill health kept him from a strenuous practice and he turned to biography and studies of the relations between American constitutions and the courts. Besides his biographies of Charles Jared Ingersoll (1897), Thomas Hart Benton (1904), and John C. Calhoun (1917), his legal works include *The Relation of the Judiciary to the Constitution* (1919).

MEIJI, mā-ē-jē, "enlightened government": the name given the period from 1867 to 1912 in Japanese history. Until the Gregorian calendar was adopted in 1875, the Japanese fixed historical dates according to the *nengo,* or year-period. The beginning and ending of a *nengo* was originally fixed arbitrarily, but was later made to coincide with the emperor's reign, so that the 33rd year of Meiji was 1900, Mutsuhito (q.v.), whose reign title was Meiji Tenno, having succeeded to the throne in 1867.

MEIKLEJOHN, mīk'l-jŏn, **Alexander,** American educator: b. Rochdale, Eng., Feb. 3, 1872. He was educated at Brown University and at Cornell. He taught at Brown from 1897 until 1912 when he became president of Amherst College. He resigned this position in 1924, and in 1926 became professor of philosophy at the University of Wisconsin where, the following year, he put into effect a far-reaching experiment in higher education, an attempt to combine the individual attention possible in a small college with the greater facilities of a large university. Students and teachers were brought closer together, and individual instruction and group discussion were substituted for the conventional classroom lectures. Included in his writings are *The Liberal College* (1920); *Freedom and the College* (1923); *The Experimental College* (1932); *Free Speech and its Relation to Self-Government* (1948).

MEILHAC, Henri, mā-yăk, French dramatist: b. Paris, Feb. 25, 1831; d. there, July 6, 1897. Much of his work was done with Ludovic Halévy (q.v.). They furnished the book for Offenbach's *La Belle Hélène* (1864), *Grande-Duchesse* (1867), *La Périchole* (1868), and *Les Brigands* (1869). Among his independent plays are *Décoré.* In 1888 he was elected to the Académie française.

MEILLET, mā-yā, **Paul Jules Antoine,** French philologist: b. Moulins, France, Nov. 11, 1866; d. Paris, Sept. 22, 1936. He studied in Vienna and Paris, becoming a professor of the École des Hautes Études, Paris, in 1891. Commencing with the Slavic group, he gradually extended his knowledge of languages until it embraced all of the Indo-European family. His *Les Dialectes Indo-Européens* (1908) traces the modern differences between the members of that family back to what were originally variations in dialect. Besides a search for rules which would be applicable to all languages in tracing their development, his works stress the importance of the social changes reflected in linguistics. He was the author of works on Old Slavic, Old Persian, classical Armenian, Latin and Greek, as well as on the Germanic languages.

MEININGEN, mī'nĭng-ĕn, Germany, a town in Thuringia, formerly capital of the duchy of Saxe-Meiningen, in the narrow, wooded valley of the Werra, 40 miles southeast of Erfurt. It is an attractive town with handsome streets, having been practically rebuilt since the disastrous fire of 1874 which destroyed the old town, but a church built by the Emperor Henry II and a 17th century ducal palace survived. The stock company of a local theater which for 16 years enjoyed a European reputation for the excellence of its acting and staging, and which helped to turn the German theater towards realism, was dissolved in 1890. Local industries include brewing, chemicals and textiles. Pop. 22,189 (1939).

MEIN KAMPF (MY STRUGGLE). The National Socialist "bible" was dictated by Adolf Hitler while he was imprisoned in the fortress of Landsberg on the Lech following the unsuccessful putsch of 1923, and is dedicated to his followers killed in that attempt. It is primarily a propagandist essay, reading like a passionate speech designed to overwhelm the listener with its endless repetition of Hitler's views. Lacking intellectual power, it appeals to the emotions of a frustrated people. Historical facts which do not suit Hitler's purpose are warped or omitted. The highest race, Hitler says, is the "Aryan" of which the purest strain is the German, but a world-wide conspiracy of Jews, whom he calls the lowest race, keeps this Master Race

divided and threatens to destroy it. This can be averted only by uniting all Germans, including those living beyond the boundaries of Germany, into one, pure racial state. "Aryan" races which mix their blood with that of inferior peoples perish because they lose the force of resistance contained only in the pure blood. Germany, therefore, must be made internally strong by the elimination of all except the racially pure. Hitler lays Germany's defeat in World War I to Jewish treachery inside the nation. Like an army, the state can have but one leader. Citizens must give up their rights as individuals because the state is the embodiment of the race's will to live and the guardian of its future, and because the state has a mystic mission to enforce the domination of the Master Race over inferior peoples. Germany is to move toward the domination of Europe by installments, so that no one aggression will seem to other nations to be sufficient cause for war. In this struggle Hitler foresees two implacable enemies: France, the traditional enemy of Germany, and the USSR which, as the supporter of European communism, must be destroyed, and whose conquest will provide Germany with living-space and natural wealth. He also counts two possible allies: England and Italy. The army, Hitler says, is the finest school for the formation of character; the object of all education being to furnish soldiers for war, and mothers to continue the race. Peace makes peoples weak; only the strong, aggressive nation can survive. Hitler boldly outlines the propaganda methods he later used so successfully in his rise to power. The history of the party is traced from its humble beginnings, showing the origin of Hitler's dictatorship, which started with an unquestioning obedience inside the party and which, using the Storm Troops as its arm of violence, was to be extended over the entire nation. There is also the outline of a Socialist program which was later abandoned when Hitler found it necessary to appeal to German industrialists for financial support. Besides showing that he knew himself to be a gifted propagandist and speaker, *Mein Kampf* shows that Hitler pictured himself in a messianic role destined to save the German people; an idea his book helped him to persuade the German people to accept. That Hitler could so clearly have indicated his intentions in 1923, without being stopped short of the point where Germany by 1939 had become stronger than its former enemies of World War I, can only be explained by the lack of unity among the former allies, each of which sought its own advantage after the end of that war; by a guilty feeling in these latter countries that Germany had been too harshly dealt with after World War I; and by the futile hope that no people which had experienced the horrors of World War I would follow its leader into the bloody catastrophe of World War II.

JOHN LEE DE WITT,
Editorial Staff, "Encyclopedia Americana."

MEISSEN, mī'sĕn, Germany, a town in Saxony founded by Henry I about 928, on the Elbe at the confluence of the Meisse and the Trierbisch, 14 miles northwest of Dresden. The town was severely damaged during the Thirty Years' War and again during the Seven Years' War. Russian troops, in their advance into Germany, reached the Elbe near Meissen on April 23, 1945, three days before they contacted the American Ninth Army near Torgau. Overlooking the town is a noble castle originally built in the 10th century and rebuilt in the 15th century and one of the finest early Gothic cathedrals in Germany. So-called Dresden china, the first hard porcelain made in Europe, developed by Johann Böttger, or Boettcher (q.v.), has been manufactured here since 1710. It achieved widespread popularity during the 18th century, but Meissen lost its pre-eminence during the Seven Years' War when the town was taken by Frederick the Great who received a tribute in porcelain, but deported some of the best craftsmen. The town manufactures matches and stoves, and has machine-works and breweries. Pop. (1939) 47,833.

MEISSONIER, mā-sŭn-yā, **Jean Louis Ernest,** French genre painter and etcher: b. Lyon, France, Feb. 21, 1815; d. Paris, Jan. 31, 1891. He came to Paris in early youth and entered the studio of Léon Cogniet, meanwhile forming his style on the Dutch masters as represented in the Louvre. He first attracted attention by his illustrations of the Bible, Bossuet's *Universal History; Orlando Furioso, Paul and Virginia,* etc. His earliest paintings in genre to be exhibited in the Salon were *The Little Messenger* and *The Chess Player* (1836). His reputation grew rapidly on the successive appearance of *The Monk* (1838); *The English Doctor* (1839); *The Game of Chess* (1841). The times of Louis XIV and Louis XV with all the accessory richness and variety of costumes, weapons and domestic luxury, found in him their most successful delineator. In the many canvases which he produced in this narrow department of genre he showed a keen and strong, but not too florid, power of characterization, which was accompanied with a marvelous technique in the handling of stuffs and metals. But modern history eventually claimed his attention. He followed the army of Napoleon III to Italy in 1859 and later found a congenial field for the exercise of his special gifts in the campaigns of Napoleon I. His pictures were often small, but finished with minute and delicate virtuosity, a good example of which may be seen in his *Cuirassiers of 1805,* but he is considered less successful in large canvases and elaborate figure compositions than in his small paintings. Among his most famous pictures of the Napoleonic cycle are *Napoleon I with his Staff* and *Napoleon III at Solferino* (1864); *Napoleon I at Friedland* (1875), now in the Metropolitan Museum of New York.

MEISTERSINGER, mīs'tĕr-zĭng'ĕr, or **MASTER-SINGERS** (Ger., *Meistersinger*), a society of German singers formed in the 14th century. During the long evenings of winter the worthy burghers of the German cities assembled to read the poems of the minstrels. Some of the hearers were naturally led to try their own skill in verse; others followed, and the spirit of the age soon embodied these votaries of the muse into societies after the fashion of corporations. Charles IV gave them a charter and a coat of arms. They met on certain days and criticized each other's productions, in which external correctness seems to have appeared to them the chief object; few, indeed, had an idea of the difference between poetical and prosaical ideas or expressions. Their attempts in the lyric style were chiefly limited to spiritual songs; in the epic to rhymed versions of the scriptural narratives. They were also

ond of the didactic style. The rules by which he members of the societies were to be guided s to the meter, etc., of their compositions were ritten on a table, and called *tabulatur*, for the ake of enforcing a strict observance of purity n language and prosody. The chief faults to e avoided were collected; they were 32 in num-er, and distinguished by particular names. He ho invented a new meter, invented also a new une, the names of which were the drollest and ometimes the most senseless imaginable. Be-ide their stated meetings they held public neetings, generally on Sundays and festivals n the afternoon in churches. In Nuremberg, here the mastersingers flourished particularly, uch meetings were opened with free singing, n which anybody might sing, though not belong-ng to the corporation. In this the choice of the ubjects was left comparatively uncontrolled; hen followed the chief singing, when only those ho belonged to the corporation were allowed to ing, and only on scriptural subjects. The judges ere called *Merker*, and sat behind a curtain. here were four: one watched whether the song as according to the text of the Bible, which lay pen before him; the second whether the prosody as correct; the third criticized the rhymes; ne fourth, the tunes. Every fault was marked, nd he who had fewest received the prize, a chain ith medals. Whoever had won a chain was llowed to take apprentices, to have many of hom was a great honor. Money was never aken from apprentices. After the expiration f his poetical apprenticeship the young poet as admitted to the corporation, and declared master after having sung for some time with cceptation. These strange societies originated oward the end of the 14th century at Mainz, trassburg, Augsburg and continued in several ree cities of the empire until the 17th, in Nu-emberg to the 18th century, where probably he renown of Hans Sachs (q.v.), the famous hoemaker and poet, kept them longer in exist-nce.

MEITNER, Lise, Austrian physicist: b. ienna, Nov. 7, 1878. As assistant to Otto Hahn n Berlin and professor at the Kaiser Wilhelm nstitute there, she became one of the world's oremost women nuclear physicists. With the ise of the Hitler regime, she was forced to ee, going to Bohr's Institute in Copenhagen. he came to the United States in 1946 to join he faculty of the Catholic University, Wash-ngton, D. C. Her researches have included tudy of continuous beta-ray spectra, positron mission from heavy nuclei and neutron disinte-rations. After her experiments with Otto Hahn n the uranium reaction, she, with Otto Robert risch, showed that the process occurring was splitting of the uranium nucleus. This phe-nomenon, now called fission, was utilized in the levelopment of the atomic bomb.

MEKONG, mā-kŏng', a large river of south-astern Asia, which rises in Tibet, passes through unnan (a province of China), Laos, Cambodia, nd French Cochin-China, and falls into the hinese Sea by several mouths, after a course f about 2,600 miles. Its navigation is much in-errupted by sandbanks and rapids. The Tonle ap, a lake covering an area of 100 square miles n the dry season and 770 square miles in the ainy season, in the southwestern part of Cam-odia, receives the flood waters of the Mekong.

MELA, mē'lȧ, **Pomponius,** Spanish geographer of 1st century A.D. and author of *De Situ Orbis* containing concise view of the then-known world.

MELAMPUS, in Greek mythology, son of Amythaon, who was the first mortal endowed with the gift of prophecy, and who first practiced the medical art. He is said to have introduced the worship of Bacchus into Greece. According to the legend, he could converse with animals, and was favored by Apollo, who taught him divination. His powers saved his life when he was imprisoned in Thessaly. The worms in the wall informed him that the structure would soon fall, and he told his jailers, who withdrew, taking him with them. They informed the king and Melampus was at once in demand, courted and feted. He married one of the king's daughters and was given large estates. In ancient Megaris he was worshipped and a temple erected in his honor.

MELANCHOLIA. See INSANITY.

MELANCHTHON, Hellenized name of PHILIPP SCHWARZERD (Eng. "black earth"), German reformer: b. Bretten, in the Palatinate, Feb. 16, 1497; d. Wittenberg, April 19, 1560. He was left an orphan in his 10th year and taken into the house of his grandmother, a sister of Reuchlin (see REUCHLIN, JOHANN), the great German humanist, by whom he was affectionately treated and encouraged in his studies. In his 12th year he entered the University of Heidelberg and two years later was graduated bachelor. While he was occupied as tutor to the son of Count von Löwenstein, he continued to give attention to his own progress in Greek; in 1514 was made master of arts at Tübingen and thenceforth devoted himself to humanism, lecturing on Cicero, Terence, and Greek grammar. He also gave much time to the study of theology, jurisprudence and medicine. Here he first became acquainted with Erasmus' edition of the New Testament, and was through the influence of Reuchlin elected professor of Greek in the newly founded University of Wittenberg. He delivered an inaugural address (Aug. 29, 1518), *De Corrigendis Adolescentiae Studiis,* which produced a revolution in German educational methods and above all met with the approbation of Luther, professor of philosophy at Wittenberg. From this time Melanchthon became *Preceptor Germaniae* (The Schoolmaster of Germany), and the Ally of Luther. These two champions of the Reformation were brought still closer together by their union at the Leipzig Disputation (1519), in which they were confronted by Dr. Eck (see ECK, JOHANN VON), the great opponent of Luther and the movement he was inspiring. In his handling of this adversary, both orally and by his writings, Melanchthon showed himself to be the leader of Protestant controversialists and the most learned, judicious and ready of Protestant disputants.

In 1520 he married Katharina Krapp, daughter of the burgomaster of Wittenberg, and Master Philip, as he was familiarly called, as he settled down to domestic life, was placed on the theological faculty of the university, and the first fruit of his increased application to the theological study and teaching was his *Loci Communes Rerum Theologicarum,* which was

the first declaration of the Protestant position delivered in formal terms of dogmatic theology. The volume ran through 60 editions in his lifetime, and established its author's position as Luther's complement — in some respects the lesser spirit of the Reformation movement, but the scientific talent which supported on the intellectual side the genius and the faith of Luther. Melanchthon, by his historic learning, by his power over the classic languages, was enabled to communicate to the learned world the real principles of the new movement and the facts of the past on which it was founded. He brought to bear his deep knowledge of theological philosophy, his acquaintance with the precise terms in Greek and Latin of scriptural, patristic and scholastic statement on the main question of the dispute, and he had the calmness of the well-balanced humanist which enabled him to direct with cool and even mind the movements of his party and to keep it as free as possible from the fury and blindness of intolerance. His knowledge of Greek made him invaluable to Luther in translating the Bible. His pen had an immense influence in securing the after success of the initiative taken by bolder but less cautious and reasonable spirits, and left a mark on the German Reformation deeper, more permanent and characteristic than that of any among his most enthusiastic contemporaries. His *Epitome Doctrinae Christianae* became from the first an influence which establishes its claim to be called the pandect and code of European Protestantism.

The spirit of Melanchthon was distinctly conciliatory. The Reformation had resulted not only in a German revolt from the papacy, but in the creation of a host of jarring Protestant sects. Melanchthon's broad and far-seeing spirit was averse to division of any kind. The Augsburg Confession (q.v.), which was presented to the diet in 1530, surprised even the Roman Catholics by its moderate tone. It was drawn up by Melanchthon in accordance with memoranda supplied by Luther and it has all the breadth, calmness, and judicial cautiousness of Luther's friend and good genius. But this spirit of compromise, hopefulness, and patience was out of harmony with the passion for controversy which made Wittenberg a center of storm and strife. Melanchthon, however, stuck to his post at Wittenberg long after the great power and influence he once wielded had passed from him into the hands of more positive, violent, and aggressive leaders. There occurred a breach between the Philippists, the followers of Melanchthon, and the Lutherans, who adhered to the extreme views of his friend on the subject of free will and irresistible grace, on the doctrine of the Lord's Supper, and on the adiaphora (indifferent matters), as the former was inclined to term the ceremonies of the Roman Catholic Church. He and his followers were assailed as "rogues" and "worshippers of Baal." Luther stated his own views on the sacrament with such violence that the recollection of his *Short Confession Respecting the Lord's Supper* filled him with remorse on his death bed, where he acknowledged to his friend "Dear Philip, I confess to have gone too far in the affair of the Sacrament." The death of Luther left Melanchthon to the mercy of such zealous and fiery sectaries as had been engendered in that teeming period of intellectual and theological movement, which the monk of Wittenberg had inaugurated. He survived Luther by several years, waiting for death, he said "as a refuge from the frenzy of theologians," and praying that the Protestant world might find its way at last to reunion, a prayer which as yet remains unfulfilled.

Melanchthon's important part in the Reformation movement has often been lost sight of in the blaze of Luther's more striking and popular personality. Yet he may with some reason be called the brains of the Reformation. More than that, he was a man who, while he stood for progress, was averse to revolutionary change. He was a constructive rather than a destructive religious reformer; he could affect his generation only by presenting an example of intellectual refinement, moderation, tolerance, and conservation, which the warring giants of the Reformation refused to follow. In 1865 a statue was raised to him at Wittenberg and in 1883 a group comprising Melanchthon and Luther at Leipzig. He was the author of many books, including theological and controversial treatises, commentaries on the classical authors, and works on history and philosophy. His works are found complete in the 28-volume *Corpus Reformatorum* (1834–1860). Consult biographies by George Wilson (London 1897); J. W. Richard (New York 1898), Karl Hartfelder (Berlin 1899); Georg Ellinger (Berlin 1902).

MELANESIA, měl-à-nē'shĭ-à (Gr. *melas* black; *nēsos,* island), collective name for the great southwesterly division of the Pacific Islands (see OCEANIA). The insular groups comprising Melanesia lie, from north to south, between the equator and the Tropic of Capricorn; and from west to east they are bounded, respectively, by New Guinea and the Fiji Islands. The division is named for the extreme blackness of the people rather than of the islands themselves, for the Melanesian (q.v.) is dark-skinned and Negroid. Some of his ancestors migrated from Indonesia to New Guinea, where they intermingled with the Papuans, and thence moved eastward and southward through the Solomons and New Hebrides as far as New Caledonia; to the east, their migration ceased in the Fijis. Politically, the islands of New Caledonia belong to France and the New Hebrides constitute a Franco-British condominium. Fiji is a British colony, and the British Solomon Islands Protectorate comprises all save the northernmost of the Solomons. Bougainville and Buka, most northerly of the Solomon Islands, and the Bismarck Archipelago (comprising New Britain, New Ireland, Lavongai, and Admiralty Islands) are part, politically, of the Territory of New Guinea, the designation for former German colonies in Melanesia captured by the Australians in World War I and subsequently administered by the Commonwealth, at first as a League of Nations mandate and later as a United Nations trusteeship. The political components of Melanesia are discussed in articles under their names.

Although Melanesia still awaits a systematic geological survey, it is known to be highly mineralized. Gold has for long been mined in Fiji and the Solomon Islands, and nickel, chrome, and other minerals are worked in New Caledonia. Sugarcane is the most important agricultural product throughout Melanesia, and in many parts of the division rice, coffee, cacao, and rubber are of great economic value. North and

northeast of Melanesia lie, respectively, Micronesia and Polynesia (qq.v.), the other main divisions of the Pacific Islands. Consult Blackwood, B., *Both Sides of Buka Passage* (London 1935); Wood, G. L., *The Pacific Basin: A Human and Economic Geography* (Oxford 1942); McGuire, Paul, *Westward the Course: The New World of Oceania* (London 1943); Robson, R. W., ed., *The Pacific Islands Handbook* (New York 1945).

MELANESIAN, a term denoting the dominant ethnic stock in Melanesia (q.v.). It was formed by the intermingling of an aboriginal black, wooly-haired population of Papuan origin with an immigrant Indonesian stock which had been previously modified by proto-Malayan blood and culture. However, the Melanesians vary considerably in type and language. In some parts of the New Hebrides and the southern Solomon Islands there are numerous small, primitive, and physically debased tribes very close to the lowest level of savagery who practice polygamy, infanticide, and cannibalism; but in the western Solomons the people are fine, upstanding specimens with intensely black skins. Tongan (Polynesian) blood has mixed with Melanesian in the eastern group of the Fijian Islands to produce a handsome, intelligent, well-built race with a light copper-colored skin; while the Fijians are characterized by tall, fuzzy hair, in the northern Solomons the hair of many tribes is straight or only slightly wavy. Excepting in the Fijis, where one language is spoken throughout the islands, the differences of speech between island and island, and even between village and village on the same small island, amount to complete incomprehensibility. Thus there has come into widespread use a primitive form of "pidgin" English with most limited vocabulary which is employed as a lingua franca not only by the Melanesians but also by French and German missionaries and traders among them. Missionary effort in Melanesia has followed the flag for the most part, although in the interior of some of the larger islands, and particularly in the northern New Hebrides, there are large numbers of savage peoples which have not yet come under civilizing influences. Those who have been long engaged in evangelizing among the Melanesians include the Church of England, Presbyterian, Methodist, London Missionary Society (Congregational), Roman Catholic, Evangelical, and Seventh Day Adventist missionaries. Consult Fox, C. E., *The Threshold of the Pacific* (London 1924); Mytinger, Caroline, *Headhunting in the Solomon Islands* (New York 1943); MacQuarrie, H., *Vouza and the Solomon Islands* (London 1945).

MELANISM, an excess of pigment in the skin and its appendages, producing real or comparative blackness; the opposite of albinism (q.v.). Melanism is less frequent than albinism, but more inclined to affect large numbers of individuals of a species, forming melanistic varieties and is seen not only in man but in other mammals; and in birds, reptiles, fishes, and in insects as, for example, certain moths which are found in Labrador and in the White Mountains of New Hampshire, showing a possible connection between melanism and cold or high altitudes. Moisture is also considered to be a determining factor, as is indicated by the fact that the darkest races of men inhabit the warmest and dampest regions of the earth. A conspicuous example of melanism is afforded by the American black squirrels, which are melanistic varieties of various species, especially the fox squirrel (*Sciurus niger*) and the gray squirrel (*S. carolinensis*). These varieties prevail in certain parts of the United States, as the region of the Great Lakes and upper Mississippi Valley, and rarely occur elsewhere. Thus a black squirrel is almost unknown in New England or the Hudson Valley. Another familiar example is found in the black leopards, which in a direct light seem absolutely black, but under reflected light betray a pattern of spots similar to those of the ordinary leopard. Such examples, as is the case with other melanistic animals, often occur in the same litter of young with normal forms. In many of the lower animals, as butterflies, melanistic tendencies are developed under certain conditions, especially of excessive moisture. The pigments in the skin are mainly of the class called melanins, which produce dark hues. Total abnormal melanism in man is unknown, but cases of partial melanism are on record. In one instance one half of the face was white, the other black. A case is on record of a 16-year-old girl, a laundress, whose neck, face, and upper chest became blue on certain occasions. She was otherwise apparently normal, but the skin was so pigmented that when she blushed her color was blue instead of red, the change appearing with chameleonic rapidity and being associated with the accession of blood to the skin. A white towel was stained blue by being rubbed over her skin. Other cases of skin discoloration are that of a man who became black in places and yellowish brown in others and that of an unmarried woman white until she was 21 and thereafter black as a Negro. The cause of this condition is unknown. Melanoderma, chloasma, and liver spots are terms applied to irregularly shaped yellow, brown, and black colorations of the skin. Some of these spots are due to scratching following the bites of body vermin, to prolonged pressure upon a portion of the skin, prolonged use internally of preparations of silver, to racial admixture, or to general diseases, such as cancer or tuberculosis. See Coloring Matters; Coloration, Protective.

MELANITE, a very black variety of garnet especially the lime-iron variety, in which lime largely preponderates in the protoxides. Melanite occupies a place midway between schorlomite and the garnets pure and simple; this is notably true of the sort containing the rare element titanite (q.v.). The group includes all the darkish garnets, with the exception of the precious garnet, technically the pyrolite, which varies from red to black. With the green demantoids the blackish melanites make up the greater part of Dana's second class of garnets, the iron garnets.

MELANORRHOEA, mĕl-ȧ-nŏ-rē'ȧ. See Varnish Tree.

MELASMA, a disease marred by discoloration of the skin. The term is rightly used in connection with a pigmentation of the skin, sometimes diffuse (color varying—dusky yellow, greenish brown, or even

black), and believed to be dependent upon degeneration of the suprarenal capsules or the semilunar ganglia. (See ADDISON'S DISEASE). Sometimes the term is applied to the conditions known as liver-spots and "moth-patches."

MELASTOMACEÆ. See DEER GRASS.

MELBA, Nellie, Australian prima donna: b. Melbourne, about 1860. She studied there in the Presbyterian Ladies' College; then took up music under Marchesi in Paris. On 15 Oct. 1887 she made her début in Brussels in 'Rigoletto'; at that time gave up her family name Mitchell and took the stage name Melba, which is said to have been suggested by the name of her native city; in 1889 she appeared in Paris at the opera, where she stayed for three years, during which she appeared in London in Italian répertoire; and after 1892 toured Europe and America. Her best rôles were Ophelia, Juliette, Lucia and Nedda in 'I Pagliacci.' She was created Dame of the British Empire in 1918. She published her 'Melodies and Memories' (1925). She died 23 Feb. 1931.

MELBOURNE, mĕl'bĕrn, **William Lamb,** VISCOUNT, English statesman: b. 15 March 1779; d. 24 Nov. 1848. Carefully trained by his mother, he entered Eton in 1790, Trinity College, Cambridge, in 1796, and Lincoln's Inn in 1797; studied law in Glasgow; was called to the bar in 1804; and in 1805 was elected to the House of Commons, where he followed Fox, leader of the opposition. He lost his seat in 1812 because of his vote for Catholic emancipation; was returned in 1816; served as chief secretary in Ireland in 1827; and in 1828 entered the House of Lords upon his father's death. Only then did he begin to figure in politics, and that only because of his popularity, for he had no official ability, being neither diligent nor brilliant. As home secretary under Grey in 1830 he was a failure; but in July 1834 the king induced him to form a ministry, and again in 1835, in spite of the king's effort to foist Peel on the country in November 1834, he became Premier. He remained in office until August 1841, thus covering the early years of the reign of Victoria, whom Melbourne ably instructed in the duties of her position. His tuition of the young queen seems, however, the only event of his long administration, and he must be classed rather as a politician than as a great statesman, since he was scarcely more than indifferent to the reform measures of the day. He was a man of much learning, of a rather attractive, though coarse and habitually profane, wit and of a strange admixture of constitutional conservatism and political liberalism. His wife, Lady Caroline Ponsonby, whom he married in 1805, was separated from him in 1825; she wrote several novels and was a friend of Lord Byron. See NORTON, CAROLINE ELIZABETH; and consult Torrens, W. M., 'Memoirs.'

MELBOURNE, Australia, the capital of the state of Victoria, the second largest city of Australasia, situated around Hobson's Bay, at the northern extremity of Port Phillip, 40 miles north of its entrance from the ocean between Points Lonsdale and Nepean. The city and its numerous suburbs occupy an extensive undulating area, with the Yarra River, a stream of no great size, winding through it. The central and most important business part of the city is on the north bank of the Yarra, two miles by a direct railway line from the river's outlet in Hobson's Bay, but nine miles by the meandering water route. The city is built on a rectangular plan with fine wide streets lined with handsome and substantial public buildings and residences. Numerous lines of railway connect with the interior and the extensive suburban districts, which include such important places as Collingwood, North Melbourne, Fitzroy, Carlton, Brunswick, South Melbourne, Richmond, Prahran, Saint Kilda, Port Melbourne, etc. The city is well lighted, and paved, and is abundantly supplied with water, while millions of dollars have been expended on a new and perfect system of drainage and sewerage.

The public buildings of Melbourne are noteworthy. The Houses of Parliament contain the State Legislative Assembly and Council. Government House is a palatial building, conspicuous from every part of the city, with a tower 145 feet high. Other public buildings include the law courts, forming an extensive square, the post-office, the custom-house, the treasury, the land and mining offices, the mint, the free library with some 300,000 volumes; the university, with an admirable museum belonging to it and a splendid hall (the Wilson Hall) in the Gothic style; the Ormond Presbyterian College; the town hall, with a large assembly room containing a splendid organ; the exchange, observatory, meteorological station, and athenæum. The ecclesiastical buildings include an Anglican Cathedral, a Roman Catholic Cathedral and the Scots church, with a fine steeple. There are several "sky-scraper" office and store buildings; many banks and business premises are attractive; and the Exhibition building deserves notice. At the head of the educational institutions is Melbourne University (with over 250 professors, lecturers, and teachers), with which are affiliated the four denominational colleges, Trinity (Episcopal), Ormond (Presbyterian), Queen's (Methodist) and Newman (Roman Catholic). Charitable and benevolent institutions are numerous. There are several parks and other grounds for public recreation, and among these the Botanic Garden deserves special notice on account of its extent (100 acres), its beauty, and the value of its collection of trees and plants. The beautiful Fitzroy Gardens also deserve special mention. Melbourne is the see of a Roman Catholic archiepiscopate and of an Anglican bishopric. The United States is represented by a consul-general. The chief industrial products of Melbourne are leather, furniture, clothing, flour, ales, cigars, ironware, woolens, etc. The shipping trade is large both in exports and imports, the chief of the former being wool and gold, of the latter manufactured goods. Most imports are subject to a heavy duty. Vessels of 26 feet draught can ascend the Yarra. Its navigation has been much improved, and the Coode canal shortens the passage. The largest vessels are accommodated at Port Melbourne and Williamstown, with depths of about 36 feet both on Hobson's Bay; Port Phillip Bay affords unlimited anchorage for the largest vessels. The tonnage of vessels entered 1936–37 was 8,173,042. Pop. of Melbourne, including the suburban municipalities, 1,000,000, more than half the population of the state.

The first settlements on the site of Melbourne were made in 1835, and a year or two

atter it received its present name, being so called after Lord Melbourne, who was then British prime minister. It was incorporated in 1842 and became a bishop's See in 1849. In 1851 it became capital of Victoria (then established as a separate colony), and received an immense impetus from the discovery of gold fields.

A centennial exhibition was held in 1888 in celebration of the founding (in 1788) of the Australian colonies. A great conflict between labor and capital took place in 1890, and a strike by the labor-unionists took place on a very extensive scale both in Victoria and New South Wales. In 1892–93 Melbourne suffered severely from commercial depression, financial crises and banking disasters. The first Parliament of the Commonwealth of Australia was opened in the Exhibition Building on 9 May 1901 by the Duke of Cornwall and York (afterward George V). Consult 'Victoria and its Metropolis, Past and Present' (1889); Gordon and Gotch, 'Australian Handbook' (1928).

MELCHERS, Paulus, German cardinal: b. Münster, Westphalia, 6 Jan. 1813; d. Rome, 14 Dec. 1895. He studied law at Bonn and theology at Munich and Münster; was ordained priest in 1841; in 1857 became bishop of Osnabrück, and in 1865 Pope Pius IX nominated him archbishop of Cologne. At first opposing the doctrine of papal infallibility at the Vatican Council, Melchers afterward accepted it, in agreement with the majority, and dealt severely with professors who sought to prevent its declaration. In the Kulturkampf (q.v.) his conspicuous activity brought him into collision with the representatives of government, and in 1876 he was removed from his archbishopric. His writings include 'Eine Unterweisung für das heilige Altarsakrament' (1878); 'Die katholische Lehre des Herrn' (1883), and 'Das Leben der allerseligsten Jungfrau und Gottesmutter' (1884).

MELCHITES, mĕl'kīts, those Christians of western Asia and of the Levant who acknowledge the supremacy of the Roman Pontiff and accept the dogmas of the Roman Catholic Church. The Syriac and Egyptian congregations of this name in the main belong to the Greek Church though in some unimportant matters of ceremony and discipline they take an independent course. They are, however, under a chief bishop of their own, who is styled patriarch of Antioch. The term Melchites is a nickname. It means «Royalists» and was given to them by the orthodox Greeks with the implication that they accepted the decrees of the Council of Chalcedon merely at the dictation or in conformity with the example of the emperor. Celibacy is imposed upon their bishops, but their priests are at liberty to marry. Their liturgy is in the Arabic language; they use unleavened bread in the Eucharist and in their monastic houses they follow the Basilian rule. There are said to be 100,000 of them. Consult Neale, 'History of the Eastern Church.'

MELCHIZEDEK, mĕl-kĭz'ĕ-dĕk («king of righteousness," that is, righteous king), in the story of Genesis, king of Salem and priest of «Supreme God." He met Abram on his return from the victorious expedition against Chedorlaomer, gave him his blessing and received tithes from him. The antelegal king-priest stands in Psalm cx as a figure typical of the Messiah the vicegerent of Jehovah, and in Hebrews vii, 3, of the kingly priesthood of Jesus. There are various views as to the identity of Melchizedek, as he is named in many ancient writings. Rabbi Kaufmann Kohler of the Hebrew Union College, Cincinnati, states in the 'Jewish Encyclopedia' that the personality of Melchizedek rests upon ancient Jewish tradition, and identifies him with Malki-Zedek, first king of Zedek, the ancient name of Jerusalem. Philo speaks of him as the «Logos»; others believe he was Shem, ancestor of Abraham. The chapter in Genesis containing his story is a unique passage of the Pentateuch, and according to Wellhausen is one of its latest additions. Ewald counts it the earliest portion of the history and based on old Canaanitish records; others, as Nöldeke, explain it as utterly unhistorical.

MELCHTHAL, mĕlH'täl, **Arnold von** (Arnold an der Halden), Swiss patriot. He is considered by some authorities to be a mythical character, but was supposed to have lived in the 14th century. He incurred the wrath of the governor and was compelled to flee to escape punishment, whereupon the governor seized Arnold's aged father and had his eyes put out. The son, enraged at this barbarity, with two friends planned a revolt against the Austrian power which they successfully conducted. Consult Ægidius Tschudi, 'Chronicon Helveticum' (1505–72).

MELDOMETER. See Melting Point.

MELEAGER, according to Greek legend, the hero of the Calydonian boar hunt. The earliest form of the story is found in the 'Iliad,' according to which Meleager is son of Æneus, a king of Ætolia, and Althæa, daughter of Thestius. When the boar had devastated the land Meleager gathered a band about him and after a great struggle and with considerable loss of life slew the monster. A quarrel over the spoils arose between the Ætolians and the Curetes, the latter being under the leadership of Meleager's maternal uncles. In the quarrel the latter were killed by Meleager, who was now cursed by his mother, who prayed the Furies and gods of the nether world to destroy him. The hero withdrew from the fight until the Curetes stormed the town when he launched forth to save his people and was slain, according to some, by the Furies, according to others by the hand of Apollo. Other versions of the story were current in later times, one of which is preserved in an ode of Bacchylides. The Calydonian Hunt was a favorite subject with artists from early times, and a copy of a work by Scopas, executed originally for one of the pediments of the temple of Athena Alea at Tegea, is now in the Vatican, Rome. In the Fogg Art Museum of Harvard University is an excellent replica of the Vatican copy.

MELEDA, Jugoslavia, an island off the southern coast of Dalmatia in the Adriatic. It is about 25 miles long and the Austrian name was Babinopolie. It is believed by some to be identical with Melita on which Saint Paul was stranded.

MELENDEZ VALDES, Juan, hoo-än' mā'lĕn'dĕth väl-dās', Don, Spanish poet: b. Ribera del Fresno, Badajoz, 11 March 1754; d. Montpellier, France, 24 May 1817. He studied law at Salamanca, where he attracted attention by his poems in the old ballad manner and was taken up by the poet Cadalso. In 1780 he received the first prize in a competition under the control of the Spanish Academy for his pastoral 'Batilo,' and, in 1784, his comedy, 'Las Bodas de Camacho,' won a prize from the city of Madrid, although unsuccessful on the stage. In Madrid he won the favor of Jovellanos, who appointed him professor of the classics in the University of Salamanca and urged him to enter upon an unfortunate political career; he became judge in 1789, a judicial chancellor at Valladolid in 1791, and fiscal in the Supreme Court in Madrid in 1797. He suffered brief exile after the fall of Jovellanos (q.v.) in 1798; but in 1802 returned to Salamanca. His sympathy with France, however, made him more than ever unpopular, and after the expulsion of Joseph Bonaparte, he went into exile in France. He was one of the most prominent figures in Spanish literary life during the 18th century.

MELETIUS, (1) founder of the sect of Meletians. He was bishop of Lycopolis in the 4th century, and antagonized Peter, patriarch of Alexandria, by refusing absolution and communion to the lapsed, that is, those who under the stress of persecution had renounced their faith. A schism resulted from the dispute and Meletius traveled through Egypt and Syria gathering thousands of followers, until the Council of Nicæa, 325, deprived him of authority and he died soon after, a merely titular bishop. (2) Another Greek ecclesiastic of the same name and century, who was made bishop of Antioch in 360, when the Arian controversy was at its height.

MELGAREJO, Mariano, mā-rē-ä'nō māl-gä-rā'hō, Bolivian soldier: b. Cochabamba, Bolivia, 18 April 1818; d. Lima, Peru, 23 Nov. 1872. He entered the army at an early age and by his courageous though somewhat unprincipled conduct in the many revolutions in his country, rose to be chief adviser of General Acha in 1862 and was made a general. In 1864 he turned against Acha who was then President, instigated a revolution and seated himself in the presidential chair. During a brief absence of Melgarejo the ex-President Belzu returned and reinstated himself in the presidency only to be shot by Melgarejo himself, who then became dictator. He crushed a revolution in 1866 and in that year formed an alliance with Spain against Peru and Chile. Revolutions followed and he was compelled to flee the country in 1871 and was killed in a quarrel at Lima.

MELIC GRASS (*mel,* honey), delicate genus of grasses growing in the shade of woods, of the order Gramineæ, having a lax panicle and spikelets of 2–5 awnless florets, of which one generally is imperfect. *M. uniflora* is of graceful and delicate appearance; cattle are fond of it. This species is common in Europe. *M. nutans* is common in the United States west of the Rockies. *M. altissima,* a Siberian species, growing to the height of three or four feet, has been introduced in parts of Europe, and yields a considerable bulk of herbage. It is perennial.

MELICERTES, son of Athamas and Ino. In fear of Athamas, whose children by Nephele, Phrixus and Helle, she had tried to kill, Ino jumped into the sea with Melicertes. She became the sea divinity Leucothea, he Palæmon, whom the Romans identified with their god of harbors, Portunus. Some identify him with Moloch. It is recorded that children were sacrificed to him at Tenedos.

MELICOCCA (*μέλι,* honey — *κόκκος,* berry), genus of trees or shrubs of the natural order Sapindaceæ, comprising about six species, one of which *M. bijuga,* native of the West Indies, is there universally cultivated for its fruit. It is called the honeyberry and the Jamaica bullace plum; by the Spaniards, Monos; by the Dutch, Knipnee. It is 16 to 20 feet high. The fruit has an agreeable flavor and varies in color from yellow to jet black. It is now grown in California and Florida. When roasted the seeds may be eaten after the manner of chestnuts. Some other species also yield edible fruits.

MELIHAH, the salting of meat according to Jewish ceremonial, that it may be without blood and ritually fit for eating, thus complying with the law (Gen. ix, 4).

MELIKOFF. See Loris-Melikoff.

MELILITE, or **MELLILITE,** a native silicate of sodium, calcium, magnesium, aluminum and iron. Potassium is also commonly present to some extent. Melilite crystallizes in the tetragonal system and has a vitreous or resinous lustre and usually a honey-yellow color, from which circumstance it derives its name (Greek, "honey"). It is brittle, translucent (at least in thin layers), and distinctly pleochroic. It has a hardness of about 5 and a specific gravity of 3. The mineral occurs in basic eruptive rocks and is also observed, quite frequently, in the slag from furnaces. It is sometimes called mellite.

MELILLA, Africa, a port of Spanish Morocco, about 150 miles east of the Strait of Gibraltar. Iron ore is mined and exported. A Spanish military command is located there, a wireless station and an aviation corps, the latter having a range of 320 miles. It has been used by Spain also as a penal settlement. Pop. about 60,000.

MELILOT, a genus (*Melilotus*) of annual, biennial and perennial herbs of the family *Fabaceæ.* The species of which there are about a dozen, are natives of western Asia and the Mediterranean region and have become widely distributed in temperate and subtropical climates. They are upright, alfalfa-like plants with small yellow or white flowers which are borne from late spring until frost. The pods are few-seeded and not twisted as in the closely related genus *Medicago* (q.v.). The two best known species are yellow melilot (*M. officinalis*), an annual, and white melilot (*M. alba*), a perennial, which are common weeds in waste places, the former especially upon dry, clayey soils, the latter in damp situations. Like other members of the genus they are sweet-scented, particularly while drying, and their flowers are used to some extent for perfumery.

MELINE, James Florant, American lawyer and author: b. Sacket's Harbor, N. Y.; d.

Brooklyn, N. Y., 14 Aug. 1873. He was graduated at Mount Saint Mary's College, Emmettsburg, Md., and went to Cincinnati, where he was one of the professors at the Athenæum, and, while teaching, studied law. He was also one of the editors of the *Catholic Telegraph*. After spending some time abroad in study and travel he returned to Cincinnati, was admitted to the bar and commenced the practice of law; later he relinquished his profession and established a banking business, also holding consulates for France and other nations. In 1860 his business failed and shortly afterward he enlisted in the Federal army. He served throughout the Civil War under General Pope, attaining the rank of colonel, and after the war was for two years chief of the Bureau of Civil Affairs in the third military district. At the end of that time he went to New York and devoted himself to literary work, writing for the *Galaxy*, the *Nation* and the *Catholic World*. In the latter periodical he first published the articles controverting Froude's statements and conclusions in regard to Mary Queen of Scots; these articles, which aroused wide interest, were afterward revised and published in book form under the title 'Mary Queen of Scots and Her Latest English Historian' (1871). He also wrote 'Two Thousand Miles on Horseback' (1867); 'Commercial Traveling' (1869), and 'Life of Sixtus the Fifth' (1871).

MÉLINITE, mā'lĭn-īt, an explosive employed by the French government late in the 19th century, in charging torpedo shells and in the preparation of rupturing charges for the use of the engineer corps and cavalry in effecting demolitions. As originally used it was composed of 70 per cent of picric acid mixed with 30 per cent of pyroxylin dissolved in 45 parts of acetone. Later it consisted exclusively of fused picric acid which was poured into the shell when in the molten condition and cast there in such a manner as to leave a central canal in the mass in which the fuse terminated in a mercuric fulminate detonator by which the charge was fired. By the use of this fuse the detonation of the charge was delayed sufficiently to allow the shell to penetrate armor and reach the farther side of it before the explosion. Mélinite was very thoroughly tested at Bouchet in 1892 to determine the degree of safety that it possesses when exposed to shocks, fire and the accidental rupture of receptacles containing it, and the results were most favorable. The name, like that of other explosives, is going into disuse because of the practice of describing explosives by their principal constituents.

MELIORISM (Lat., *melior*, better), the belief that the improvement of the world by human effort is possible, and implying also the further belief that the world is *de facto* being gradually so improved and that such improvement is a law of evolution. The term was used first in conversation by the novelist, George Eliot, who desired to formulate a *via media* between the views of optimism and pessimism so prevalent in her day. Sully adopted the term in his 'Pessimism' (1877), since when it has come into general use. By Sully meliorism is described as "the faith which affirms not merely our power of lessening evil — this nobody questions — but also our ability to increase the amount of positive good. . . . By recognizing the possibility of happiness and the ability of each individual consciously to do something to increase the sum total of human welfare present and future, meliorism gives us a practical creed sufficient to inspire ardent and prolonged endeavor." The opponents of meliorism have connected it with the theory of evolution. Evolution by them is presented in a semi-religious light, inasmuch as they believe in a gradual abatement of evil through progressive evolution. This view is not confined to philosophers of this school, however, but is now the view of many agnostics, who unwarily have assumed this unconsciously religious conception of the universe. Consult Fraser, 'Theism.'

MELISSA, a plant. See BALM.

MELISSUS, mĕ'lĭs-ŭs, Greek philosopher: b. Samos, about 480 B.C. He was the son of Ithagenes, and is said to have been a friend of Heraclitus and to have commanded the fleet opposed to Pericles in 440 B.C. in the Samian War. Some fragments of a prose work of his, written in the Ionic dialect, have come down and have been collected and published by Brandis and by Mullach (1846). From these he appears to have been a philosopher of the Eleatic school and to have reached more definiteness and consistency than Parmenides. He reasoned that being was eternal, and could not have a beginning, else it would start with non-being; by like reasoning, there can be no destruction of being, for it would have to become another and opposite thing. Void he holds to be nothing, which is not, and therefore unthinkable. He concluded that being was incorporeal, because a body has size and parts.

MELITA, mĕl'ĭ-tą, the island on which Saint Paul, on his voyage to Rome, was cast away. This has generally been considered to be the Island of Malta, the ancient name of which was Melita, and one of whose bays has from immemorial time borne the name of Saint Paul; but some critics have attempted to prove that it was an island, the modern Meleda (q.v.), on the coast of Dalmatia, in the Adriatic.

MELKART (Phœnician, "God of the City"), name of the presiding deity of the city of Tyre and of the whole Tyrian nation, namely, Baal (q.v.), the sun god. He is sometimes identified with the Heracles or Hercules of the Greeks. He was the patron god of mariners and the Phœnician colonies of the West, in Africa and Spain, were under his protection. To him has been ascribed the subjugation of the savage races who anciently peopled these regions and the building of early Phœnician towns. The institution of order and legislation in these cities was also said to have been his work. Many are the voyages which he is related to have made. One of his exploits was the rescue of Astarte from the darkness in which the moon had imprisoned her in the West; he afterward made her his wife. For an account of the Temples of Melkart at Tyre consult Jeremias, 'Tyrus bis zur Zeit Nebukadnezzar' (1891).

MELKITES. See MELCHITES.

MELL, Patrick Hues, American educator: b. Walthourville, Ga., 19 July 1814; d. Athens, Ga., 26 Jan. 1888. He was educated at Amherst and after teaching for several years was appointed professor of ancient languages at Mer-

cer University in 1842 and was also ordained a Baptist minister in that year. In 1856 he was appointed to the same chair in the University of Georgia, and in 1870 he became vice-chancellor, which post he resigned in 1872. In 1878 he was appointed chancellor and in 1880 was elected to the chair of metaphysics and ethics, which offices he occupied at his death. He held several pastoral charges and was president of different conventions in addition to his educational work and published 'Baptism' (1852); 'Parliamentary Practice' (1868); 'Church Polity' (1878).

MELL, Patrick Hues, American scientist: b. Penfield, Ga., 24 May 1850; d. 15 Oct. 1918. Son of the preceding, was graduated at the University of Georgia in 1871 and was State chemist in 1874–77. In 1878 he was called to the chair of geology and botany at the Alabama Polytechnic Institute and continued in that position until 1902, when he accepted the presidency of the South Carolina Agricultural and Mechanical College. In addition to his work in the universities he was connected in 1884–1902 with the Alabama Weather Bureau and the Agricultural Experiment Station and he invented a system of weather bureau signals which has been adopted by the United States Weather Bureau. He published 'Southern Soapstones and Fireclays' (1882); 'Study of Cotton Plant' (1890); 'Life of Patrick Hues Mell, Sr.' (1895); 'Biological Laboratory Methods' (1902); etc.

MELLILITE. See MELILITE.

MELLON, Andrew William, American public official: b. Pittsburgh, Pa., 24 March 1855. He was educated at Western Pennsylvania University, now the University of Pittsburgh and entered the banking house of Thomas Mellon and Sons, eventually becoming its president as well as director in many important business and financial corporations. In 1921 he became Secretary of the Treasury in President Harding's cabinet and held the same office under Presidents Coolidge and Hoover. He was responsible for a policy of reduction in the United State's national debt due to the World War. In 1936 he gave his magnificent art collection to the nation together with $10,000,000 for the erection in Washington of a gallery in which to house it. D. Southhampton, N. Y., 26 Aug. 1937.

MELLON INSTITUTE, at Pittsburgh, Pa., founded in 1913 by Andrew W. and Richard B. Mellon, to provide qualified workers with facilities for investigating thoroughly problems of major importance in the pure and applied sciences and especially in chemistry. The institution is primarily concerned in carrying on broad researches of postdoctoral character supported by persons or organizations interested in such studies. Before establishing the institute the Mellon brothers recognized the utility of scientific research for benefiting mankind by effecting improvements in or otherwise developing technology. They set up the institute for the purpose of extending this assistance to the industries, and the institution soon demonstrated the value of its research procedure, the Industrial Fellowship System evolved by Robert Kennedy Duncan. The founders then decided to broaden the scope of the institute's activities by making available provisions for investigations in the sciences having more definite relation to human welfare, which might likewise add to technical knowledge. This basic research was begun and the entire program has since been supported generously by the founders and their families. The industrial research of the institute is organized on a contract basis, the problem being set by a person, firm, or association interested in its solution, the scientific worker being found and engaged by the institute, and an industrial fellowship being assigned for a period of at least a year. All results obtained by a fellow belong exclusively to the donor of the fellowship. Since its inception over $16,000,000 has been contributed to the institute by industrial fellowship donors, and close to $1,300,000 is being expended annually in conducting pure and applied science research.

MELLONI, Macedonio, mä-chā-dō'nē-ō mĕl-lō'nē, Italian physicist: b. Parma, 11 April 1798; d. Portici, near Naples, 11 Aug. 1854. He became professor of natural philosophy at the University of Parma, where between 1824 and 1831 he taught hygrometry. Political events having compelled him in the latter year to expatriate himself, he went to Geneva, where he made several important discoveries respecting the radiation of heat, which he presented in 1833 to the French Academy of Sciences. Later discoveries won him the Rumford medal from the Royal Society of London. Through the influence of his friends, Arago and Humboldt, he was enabled to return to Italy, and was appointed by the king of Naples director of the meteorological observatory on Mount Vesuvius. Among the results of his labors at this institution was the discovery of heat in lunar light, which led to the determination of the analogy of radiant heat to light. Political troubles again interrupted his labors, and for his presumed sympathy with liberal principles he was in 1849 ejected from his post. In 1850 he published the first volume of a work entitled 'La termocrasi, o la colorazione calorifica,' containing an account of his theory of the «coloration of light,» and of his experiments on the diffusion of heat by radiation, and particularly of its transmission through transparent media. Subsequently he gave much attention to the study of electricity and combated the conclusions of Faraday with regard to the transmission of currents over submarine wires.

MELOCACTUS, a cactus typical of the tropical American melon-cactus family, *Melocactidæ*. It consists of a globose or conical stem, having rows of spines at intervals and flowers at the top on a hemispherical or cylindrical head. There are more than 20 species. *M. communis* of the West Indies is the Turk's, Englishman's or Pope's-head cactus. The head bearing the flower is red and like a Turkish fez in form.

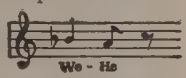
MELODEON, a musical wind instrument with a row of reeds and operated by keys. The rocking melodeon, known in America since about 1825, was unsightly, tardy in sounding and of harsh tone. Jeremiah Carhart in 1815 conceived the plan of acting on the reeds by suction instead of blowing, and reversed, to this end, the bellows and reeds, inventing the present instrument in 1836. He thus secured prompt sounding and a flute-like quality of tone; «voiced» the note by curving the reeds, and made many other improvements. In a single year 22,000 of these instruments were manufactured in the United States, and they

were popular until the cheap parlor organ displaced them.

MELODRAMA (from the Greek *melos,* song, and *drama,* action), originally and properly a half-musical drama, or that species of drama in which the declamation of certain passages is interrupted by music. It is usually a tragedy of common life, filled with surprises, acts of violence and all that excites and sustains the attention of the audience, mixed up with dancing and music and sometimes with scenes of a rudely comic character. Probability is freely sacrificed for the sake of striking situations. The object is to be sensational and to catch the applause of the gallery. See DRAMA, THE.

MELODY, *in music,* a succession of single tones so arranged as to express a musical phrase or thought. A solo for one instrument or voice with or without accompaniment is the most typical example of a melody.

Melody is one of the most comprehensive terms used in music, being properly applicable to as few as two notes or to as many as the entire principal vocal or instrumental part of a composition. An example of the first is the motif of woe in Wagner's *Der Ring des Nibelungen.*



On the other hand, the long, exquisitely mournful, unaccompanied solo for English horn in the third act of the same composer's *Tristan and Isolde,* played ostensibly by the shepherd on the stage (in reality, of course, by a member of the orchestra in the pit), is usually referred to as the shepherd's melody (or the English horn melody) from *Tristan.* Similarly the long and equally beautiful flute solo from Gluck's *Orpheus and Eurydice,* popularized by many violinists in a transcription, is universally known as the Gluck melody from *Orpheus.*

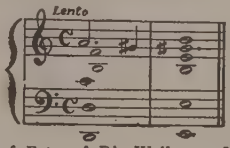
The term is also appropriately applied to a phrase, or portion of a phrase, in a part that has been subordinate to the principal one and which, for a moment, gains importance on account of its greater melodic significance. In concerted music, vocal or instrumental, the highest part is usually the melody, though as stated above, an inner one, or even one in the bass, may temporarily assume it. In polyphonic music all the parts may be equally melodic.

Melody is the outgrowth of the improvised recitative. The early Greek singer, standing before his audiences holding his four-stringed lyre or chelys, plucked a string and recited his poem on that note until fancy impelled him to change it. From this crude ancestor has sprung melody as we understand it today, which with rhythm and harmony (q.v.) form the great trinity necessary for the complete expression of music. Melody is the only one of the three capable of

suggesting enough of the other two to be satisfactory by itself. The folk song of old and the popular song of today may be sung by a single voice without any accompaniment and yet convey a very definite idea of the rhythm and something of the harmony that would naturally accompany the tune.

Melody is greatly affected by the harmony that the composer has wedded to it, and it is owing to this fact perhaps more than any other that composers continue to find it possible to write original music, for with but 12 different notes from which to form a melody it is evident that, even with all the variations that rhythm can add, the melodic material is capable of exhaustion in the enormous and growing number of compositions. The following phrases of melody, especially the first, have no particular suggestion played alone:

But with the harmony that the composers have added they have an entirely different significance,



Motif of *Fate,* of *Die Walkuere*—Wagner.

the one of great solemnity and foreboding; the other of harsh cynicism and sneering.

It is curious to note that when Wagner's music dramas were first performed, the most frequent denunciation of them made by contemporary critics was that they were "devoid of melody." By this, the critics meant that they missed the catchy "barrel-organ" tunes of the Donizetti, Bellini, and early Verdi school of opera. Some of the same critics eventually discovered that the tissue of Wagner's music was a tapestry of sound woven from much more beautiful melodies: it was literally, as the Wagner critic and biographer Henry T. Finck once put it, a case of not having been able to see the trees for the forest.

HENRY GORDON THUNDER,
Conductor, Choral Society of Philadelphia.

MELOIDAE. See BLISTER-BEETLE.

MELON-CACTUS, or **MELON-THISTLE.** See MELOCATUS.

MELONS, a popular name for several unrelated plants, but more particularly for two members of the family *Cucurbitaceae,* the muskmelon (*Cucumis melo*) and the watermelon (*Citrullus vulgaris*). The more important other fruits similarly known are the Chinese preserving melon (*Benincasa cerifera*) of the same family; the melon papaw (*Carica papaya*) of the family *Caricaceae,* and the melon-shrub or melon-pear (*Solanum muricatum*) of the family *Solanaceae.*

The muskmelon is an annual trailing herb which has been introduced by man into all tropical, subtropical and many temperate climates from southern Asia where it is native. The following are the principal varieties: Variety *cantaloupensis,* the cantaloupes, or rockmelons, which have hard, warty or scaly rinds more or less furrowed, and flesh of various colors from white to red, green or yellow. In the United States the name «cantaloupe» is loosely applied to horticultural varieties of

other groups. Variety *reticulatus* includes the nutmeg or netted melons which have softer rinds, sometimes smooth, but usually more or less netted. To this group belong the larger part of the so-called cantaloupes in American markets. Variety *saccharinus* comprises the pineapple-melons which have very sweet flesh, but are not clearly distinct from the preceding group. Variety *inodorus,* the winter muskmelons, which have less hairy, lighter-colored vines and foliage and whose long-keeping fruits are deficient or entirely lack the characteristic muskmelon odor. This group is less cultivated in the United States than in the Mediterranean region, but because the fruits can be kept until Christmas or later when properly grown, gathered before frost and slowly ripened in a cool, rather dry room, they should become more widely popular where the seasons are long enough to permit their reaching such a stage of maturity. Variety *flexuosus,* the snake-melons or cucumbers, have very long, narrow, greenish, contorted fruits, prized more as oddities than for economic uses, though often used for making preserves. They are distinct from the snake-gourds which belong to the genus *Lagenaria.* A variety *chito,* called orange-melon, melon-apple, garden-lemon and many other popular names, bears orange- or lemon-like almost scentless fruits with white or pale yellow flesh, which is grown to some extent for preserving. Variety *dudaim,* the pomegranate-melon, Queen Anne's pocket-melon, dudaim melon, etc., has small brown and yellow fruits valued solely for their exquisite perfume.

Melons are propagated wholly by means of seeds, which may be sown directly in the field or started under glass upon inverted sods, in flower-pots, berry-boxes, etc., and transplanted to the field as soon as danger of frost has passed. The former method is practised most extensively in the South and in other warm climates where the seasons are long; the latter in the North because the shortness of the season demands that the plants obtain an early start. The soil best suited to melons is a light sandy loam well drained, well exposed to the sun and well supplied with plant-food. It should be deeply plowed, thoroughly harrowed and kept clean of weeds, especially before the plants are set and until the vines cover the ground. After harrowing, the ground is marked in checks about five feet square and 10 or 12 seeds, or five or six plants, are set in each "hill," from which all but the two or three strongest vines are removed after the insects have had their share. Often, especially upon rather poor or tenacious soils, two or three shovelfuls of well rotted manure is mixed with the earth of the hills to give the plants a little impetus. The fruits are gathered when they will readily separate from the stems, preferably in the early morning.

During the closing decade of the 19th century the demand for highly flavored melons was greatly increased by the apperance in the eastern markets of the Rockyford melon, a small fruit grown in Colorado. Its appearance in large quantities drew public attention to numerous other high flavored melons grown in other sections. As a consequence many inferior varieties have nearly disappeared from cultivation. Besides the Colorado melon fields there are large areas devoted to melon-growing in New Mexico and California. New Jersey, Maryland and Delaware produce immense quantities, the first-mentioned State especially; and the product is consumed largely in the cities of Pennsylvania and New York. The Mississippi Valley States also send considerable quantities to Northern markets.

The watermelon is an annual trailing herb, a native of tropical and southern Africa, whence it has been introduced by man into all tropical, subtropical and many temperate climates for its watery sweet fruits, which sometimes weigh more than 75 pounds, but usually range between 20 and 50 pounds. The vines are more hairy, lighter green, longer running than those of the muskmelon and the leaves are deeply notched, in some cases approaching the compound form. Except for a horticultural group of firm-fleshed varieties known as preserving watermelons or more popularly as citrons, the watermelon seems to have no varieties worthy the name of sub-species or botanical varieties, and even this group appears not to have received such designation.

In general, the watermelon requires the same treatment as the muskmelon, the soil being, if anything, lighter and more sandy, and the distances between hills about double, except for the smaller growing sorts. The principal producing regions are Georgia and Colorado, but the watermelon is grown largely in all the southern States, and some of the short-season varieties as far north as Michigan and Ontario. The watermelon is more easily shipped than the muskmelon, since the tough-rinded kinds may be placed in cars two or more feet deep, the smaller specimens upon the bottom, and shipped long distances. Muskmelons, being more delicate, must be barreled or crated. The fruits are used exclusively in the raw state and have no by-products such as vinegar, sugar, syrup or brandy. The rinds, however, when deprived of the hard exterior, are often preserved with raisins, etc.

Both muskmelons and watermelons are subject to the attacks of several insects, among which the small, black, striped cucumber-beetle (*Diabrotica vittata*), the squash vine-borer (*Mellitia ceto*), the melon-caterpillar (*Margaronia hyalinata*), the cucumber flea-beetle (*Crepidodera cucumeris*), the squash-bug (*Anasa tristis*) and the melon-louse (*Aphis gossipii*) are the most important. Tobacco dust and plant protectors are largely used to prevent the attacks of the first, the adults of which feed upon the under sides of the leaves and the larvæ upon the roots. The melon-louse is fought with kerosene emulsion sprayed upon the under sides of the leaves or by fumigation with carbon disulphide. No effective remedy has been suggested for the borer. Arsenical sprays have been recommended for the caterpillars and other chewing insects. Since the insects are believed to spread diseases from plant to plant, melon-growers seek to prevent insect injury as far as possible and practicable. The diseases, of which a large number have been described, are much the same as attack cucumbers, and may be similarly controlled where control has been found possible. Some diseases, as wilt, have defied all tried remedies. This disease generally ruins the vines a week or 10 days before the fruits would be ready to harvest. Many of the complaints as to the

poor quality of eastern-grown muskmelons result from the sale of melons that have been gathered from blighted fields.

Consult Bailey, L. H., *Cyclopedia of Standard Horticulture* (New York 1944).

M. G. KAINS,
Crop Expert.

MELOPIANO, an invention by which sustained sounds can be produced on a pianoforte. It consists of a series of small hammers set into very rapid vibration by the winding up of a spring.

MELOS, mē'lŏs, **MILO,** or **MILOS,** island, Greece, in the Aegean Sea, in the southwest portion of the Cyclades, about 65 miles east of the mainland. Its length, east to west, is about 14 miles, and it is about eight miles in extreme breadth; area, 64 square miles. It is mountainous—Mount Ilias rising 2,533 feet—of volcanic formation, has hot mineral springs and mines of sulphur. The island was once famous for its riches, fertility and population, and corn, wine, cotton, oranges, and other fruits are still grown. Sulphur, manganese ore, millstone, gypsum, etc., are exported. Plaka is the principal town and nearby are the ruins of Melos, the ancient capital. Kastron is a large village on the north coast.

The island of Melos was first colonized by Phoenicians and afterward by Dorians. During the Peloponnesian War it was the faithful ally of Sparta until 416 B.C., when it was taken by the Athenians, and its inhabitants were massacred or sold as slaves. From 1204 until 1537 it formed part of the Venetian duchy of the archipelago. At the latter date it was taken by the Turks, with whom it remained till the epoch of Greek independence. Its ancient prosperity is claimed to be due largely to the fact that obsidian was found here, which was quarried and sold for making knives, hatchets and tools. In 1820 a peasant discovered here the celebrated statue known as the Venus of Milo, now in the Louvre at Paris; the Poseidon in the National Museum at Athens was also discovered here. There are numerous interesting archaeological remains, chief of which are those of the Hall of the Mystoe on the site of the ancient capital near the village of Klima, and those of prehistoric Phylakopi, which were excavated by the British School at Athens from 1896 to 1899. Pop. (1946) 6,045.

MELPOMENE, měl-pŏm'ê-nē, one of the Muses, daughter of Zeus and Mnemosyne. She presided over tragedy and was generally represented as a young woman with vine leaves surrounding her head, and a tragic mask covering her face.

MELROSE, city, Massachusetts, in Middlesex County; altitude 55 feet; on the Boston and Maine Railroad; 7 miles north of Boston. The surrounding area is largely industrial. Formerly Melrose had a number of factories, but is now primarily residential with few industrial establishments. It has a public library; parks and playgrounds; musical clubs; a soldiers' and sailors' memorial building; and, at the Mount Hood reservation, an annual winter carnival. Geraldine Farrar (q.v.) is a native of Melrose.

First setteld in 1629 and originally part of Malden, it became a separate municipality in 1650; was incorporated as a town in 1850, and became a city in 1900. It has mayor and council. Pop. (1940) 25,333; (1950) 27,750.

MELROSE, city, Minnesota, in Stearns County; on the Sauk River; altitude 1,211 feet; 97 miles northwest of Minneapolis; on the Great Northern Railroad. The surrounding region is principally agricultural, and butter, cheese, poultry and other farm products are processed here. Doors and sashes are made; also granite memorials. Melrose is a shipping and distributing point on the railroad. It was settled in 1868 on a ford on the Pembina Trail; was incorporated as a village in 1881, and as a city in 1895. It has mayor and council government, and owns its water and electric power systems. Pop. (1940) 2,015; (1950) 2,102.

MELROSE, village, Scotland, in Roxburghshire, on the south bank of the Tweed at the base of the Eildon Hills, two miles east of Abbotsford, the home of Sir Walter Scott, whose *Lay of the Last Minstrel* gave Melrose and its ruined abbey world-wide celebrity. The famous abbey, now the property of the Buccleuch family, is admitted to be the most beautiful of all the ecclesiastical ruins in Scotland. The architecture is in the late flamboyant Gothic style, and the chief remains are part of the nave, the transept, choir and the southern aisle with several chapels, of the abbey church and fragments of the cloister. The church originally was 258 feet long, with a width at the transepts of 137 feet. It was founded by King David I in 1136, destroyed by Edward II in 1322 and rebuilt by Bruce in 1326. It is the burial place of the heart of Robert Bruce, and contains tombs of Sir William Douglas, the knight of Liddesdale (1300–1353), and James, 2d earl of Douglas (1358–1388). It was partly demolished by the English in 1545. Pop. (1951) 2,146.

MELROSE PARK, village, Illinois, in Proviso township, in Cook County; altitude 617 feet; 10 miles west of Chicago; on the Chicago and North Western Railroad. It has some industries, but is mainly residential; many of its people are employed in Chicago and nearby industrial centers. The water supply system is city-owned. Pop. (1940) 10,933; (1950) 13,366.

MELTING POINT, the temperature at which the solid and liquid states of a body can coexist, without the fluid part of the mixture solidifying, nor the solid part melting. The melting point of a body which is crystalline in nature (like ice) is usually quite definite, and a body of this kind, when it melts, passes at once from a state of perfect solidity into a state of perfect fluidity. The melting point of an amorphous body, such as wax or pitch, is often very indefinite; and when a solid of this sort is gradually heated it grows soft and passes into the fluid state by a process which is practically (or even absolutely) continuous. The phenomena of the fusion and solidification of amorphous bodies like wax are not yet understood as well as those that attend the change of state of a crystalline body; and it is to be understood that what follows in the present article is stated with particular reference to the crystalline class of substances, in which the melting point is definite.

In general, solid bodies expand upon melting, the original solid having a greater density than the liquid that results from its fusion. In

the case of water, as is well known, the reverse is true; the fact that ice floats in water proving that the water is denser. The fact that the density of a substance changes upon fusion implies (as may be proved by the mechanical theory of heat) that the melting point of the substance cannot be entirely independent of the pressure. This fact was discovered in 1849 by James Thomson, who showed that the melting point of a substance like ice, which contracts upon melting, must be lowered by pressure; while the melting point of one which expands upon melting must be raised by pressure. These theoretical conclusions have since been abundantly verified by experiment. In the case of ice, for example, it has been found by Sir James Dewar, that the melting point is lowered by 0.0130°F. per atmosphere of increase of pressure, up to 700 atmospheres.

When a substance passes from the solid to the liquid state, it absorbs a very considerable amount of heat, which is known as the "latent heat of liquefaction"; and the liquid which is formed cannot be all reduced to the solid state again until an exactly equal quantity of heat has been abstracted from it. When heat is added to a mixture composed of a solid and its liquid (pounded ice and water, for example), it does not increase the temperature of the mixture, but merely causes a certain amount of the solid to melt. This continues so long as any of the unmelted solid remains; each addition of heat merely bringing about a corresponding amount of liquefaction, while the temperature of the mixture remains unchanged. It is only after all of the solid has melted that the further addition of heat will produce elevation of temperature. The melting points of compounds undoubtedly depend, in some manner, upon their molecular constitutions, but we have, as yet, no definite knowledge of the nature of the dependence. We know that in a homologous series of organic compounds, the melting points show a strong tendency to increase, as the molecular weights of the members of the series increase; but the change in the melting points is irregular as we proceed from member to member, and no law has yet been discovered which takes the changes fully into account. The melting point of a mixture (such as an alloy) is often lower than that of any one of the constituents, and the effect of the presence of an impurity in a given substance upon the melting point of that substance is often out of all apparent proportion to the quantity of impurity present. This fact implies that in the determination of a melting point it is highly important that the substance under examination shall be as nearly pure as possible. The presence of slight, unrecognized and apparently negligible impurities has sometimes led to entirely erroneous conclusions. In 1860, for example, Hermann Kolbe announced the discovery of an acid isomeric with benzoic acid, but having a lower melting point; but Friedrich Konrad Beilstein afterward proved that the substance in question was merely ordinary benzoic acid contaminated with a quantity of chlorobenzoic acid so small as to be barely recognizable by analysis.

For determining the melting point of minerals, the instrument devised by John Joly and known as the meldometer, is sometimes very convenient. It consists essentially of a strip of platinum foil, upon which small fragments of the minerals are laid. The platinum is then gradually heated by the passage of an electric current, until the mineral melts; the temperature of the foil being obtained by a calculation based upon the resistance of the platinum, the observed strength of the current and the rate at which heat is radiated from the foil, as determined by separate observations. This method is especially useful for minerals which can be had only in small fragments.

The term fusing point is often used instead of melting point, where a high temperature is required to melt. See also Freezing Point; Heat; Molecular Theory.

MELTON MOWBRAY, mĕl't'n mō'brā, urban district, England, in Leicestershire, 15 miles northeast of Leicester, on the right bank of the Wreak, at the junction of the Eye, 105 miles north by west of London. Melton Mowbray is famous for its pork pies and Stilton cheese. It owes its prosperity chiefly to being the seat of the Melton Hunt, which attracts the sporting world in great numbers during the winter months, extensive and luxurious hunting establishments being maintained here. Pop. (1951) 14,052.

MELTZER, mĕl'tsĕr, **Samuel James,** American physiologist: b. Kurland, Russia, March 22, 1851; d. Nov. 7, 1920. He received a general education at Königsberg, Prussia; studied philosophy and medicine at the University of Berlin 1875–1882 and removed to the United States in 1883, after which he practiced his profession in New York. From 1906 Dr. Meltzer was the head of the department of physiology and pharmacology at the Rockefeller Institute for Medical Research and consulting physician at Harlem Hospital. In 1917 he was commissioned major in the Medical Reserve Corps. Dr. Meltzer was a member of many medical and surgical societies. He published over 200 papers on biology, physiology, and scientific medicine.

MELUSINA, mĕl-ū-sē'nà, or **MELUSINE,** in French myths, a beautiful nymph or fairy, who is represented as the daughter of Helmas, king of Albania, and the fairy Persine; and as having married Raymond, Count of Toulouse, who built the magnificent castle of Lusignan. Like most of the fairies of that period, she was doomed to a periodical metamorphosis during which the lower part of her body assumed the form of a fish or serpent. On these occasions she exerted all her ingenuity to escape observation; but having been once accidentally seen by her husband in this condition, she swooned away, and soon afterward disappeared. Her form is said to be seen from time to time on the tower of Lusignan, clad in mourning and uttering deep lamentations. Her appearance was believed to indicate an impending calamity to the royal family.

MELVILLE or **MELVILL, Andrew,** Scottish reformer: b. Baldovie, near Montrose, Forfarshire, Scotland, Aug. 1, 1545; d. Sedan, 1622. He was educated at the grammar school of Montrose and the University of St. Andrews; studied two years (1564–1566) at the University of Paris; went to Poitiers to pursue his studies in the law; there became regent in the College of St. Marceon; and through the influence of Beza received an appointment to the chair of humanity in the academy of Geneva.

Returning to Scotland in 1574, he was at once appointed principal of the University of Glasgow, and in 1580 was made principal of St. Mary's College, St. Andrews. In 1582 he presented a petition to King James against the undue interference of the court in ecclesiastical affairs, for which he escaped imprisonment by going into England. Returning in 1585, he resumed his duties at St. Andrews, and was moderator of the General Assembly in 1587, 1589, 1594. In 1606 he was summoned to London by the king to confer on church matters, but because of his outspokenness he was committed to the Tower, and there remained until 1611. He was then released upon the solicitation of Henri de la Tour d'Auvergne (Duc de Bouillon), retired to France and became professor of Biblical theology in the University of Sedan.

MELVILLE, George Wallace, American naval officer and explorer: b. New York, Jan. 10, 1841; d. March 17, 1912. Educated at Brooklyn Polytechnic, he entered the navy as assistant engineer 1861, served through the war, and in 1879 accompanied George W. De Long's expedition on the *Jeannette* to discover the northeast passage. Of this party he was one of the few survivors; most of the others owed their lives to his indomitable courage and herculean strength—he carried a brother officer, weighing 175 pounds, upon his back, through ice and snow, at the same time superintending all movements of the crew and on occasion helping with the boat. He also commanded the subsequent search expeditions which recovered the *Jeannette's* records and De Long's body. In 1887 he was made chief of the bureau of steam engineering in the United States Navy, a post from which he retired in August 1903, having entirely reformed the service, put navy engineers on a professional rather than an artisan footing, introduced the triple screw on such successful ships as the *Columbia* and *Minneapolis,* saved the department a tremendous sum by his refusal to adopt a boiler which had proved unsatisfactory in the British Navy and designed 120 ships of over 700,000 horse power. Melville was made rear admiral in 1899, and retired in 1903. His book, *In the Lena Delta* (1885), describes his experiences in the *Jeannette* expedition.

MELVILLE, Herman, American author: b. New York, Aug. 1, 1819; d. there, Sept. 28, 1891. His grandfather, Major Thomas Melvill (original spelling of the name), was a member of the Boston Tea Party and prominent in civic affairs; in later life he became known as "the last of the cocked hats" and served Holmes as a model for "The Last Leaf." Gen. Peter Gansevoort, the maternal grandfather, successfully defended Ft. Stanwix during the American Revolution and was a leading citizen of Albany. Melville's father Allan conducted an importing business in New York which collapsed in 1830, after which the family moved to Albany, where the father died in 1832. Melville first attended the New York Male High School and later the Albany Academy, from which he withdrew after his father's death. He worked as a bank clerk, as a farm helper, and as assistant in his brother Gansevoort's fur factory, briefly attending the Albany Classical School. In 1837 he became a country schoolteacher at Pittsfield. He studied surveying and engineering at the Lansingburgh Academy in the hope of securing employment on the Erie Canal. Unsuccessful in finding a vocation on land, he went to sea in 1839 as cabin boy aboard the *St. Lawrence,* a New York to Liverpool trading ship. This experience gave him the framework for his later novel, *Redburn* (1849). Upon his return he taught school briefly in Greenbush and Brunswick (N. Y.), then traveled west as far as Illinois. In 1841 he sailed as ordinary seaman on the *Acushnet,* a Fair Haven whaling ship. After 18 months he deserted at Nukuhiva in the Marquesas Islands and spent a month among the natives of the Typee [Taipi] Valley, escaping to Tahiti on an Australian whaling ship. After further whaling experience, he enlisted in the United States Navy at Honolulu and returned home aboard the frigate *United States,* landing in Boston in 1844.

His voyages furnished materials for his best published works. *Typee,* his first book, appeared in 1846 and was greeted with an acclaim which caused him to decide on authorship as his career. In 1847 he married Elizabeth Shaw, daughter of the chief justice of Massachusetts, after publication of his second South Seas romance, *Omoo* (1847). They made their home in New York, where Melville vainly tried to secure a government appointment. After publishing *Mardi* and *Redburn* in 1849, he made a short visit to England and the continent. *White-Jacket* appeared in 1850. For financial reasons he moved in that year to "Arrowhead," a farm in Pittsfield, where he completed his greatest novel, *Moby-Dick* (1851). This was followed a year later (1852) by *Pierre.* In 1856–1857 he made a voyage to the Holy Land and then spent three seasons lecturing on the South Seas, classical art, and travel. Meanwhile, *Israel Potter* (1855), *The Confidence-Man* (1857), and several essays and short stories had appeared. After a voyage to San Francisco in 1860, he moved permanently to New York in 1863. From 1866 to 1885 he served quietly as district inspector of customs in that city.

Having turned from prose to poetry, he published *Battle-Pieces and Aspects of the War* in 1866 and *Clarel,* a long narrative poem of the Holy Land, in 1876. Two more books of poetry, *John Marr and Other Sailors* (1888) and *Timoleon* (1891) appeared in his lifetime. At his death he left among his manuscripts a beautiful short novel, *Billy Budd,* which was first published in 1924. Relatively neglected in his own day after the spectacular initial success of *Typee* and *Omoo,* Melville was rediscovered after 1919 and is now generally regarded as one of the half dozen greatest American authors. See also Moby-Dick; Omoo; Typee.

Associate Professor, Colorado State College of Education.

MELVILLE, town, Province of Saskatchewan, Canada, a divisional point on the Canadian National Railway system 280 miles northwest of Winnipeg on the main line and about 90 miles north of Regina on the Melville-Regina branch. It is in a high but productive agricultural area

(elevation 1,810 feet), the leading local industries being a flour mill and creameries. There are four public and one separate school, a Lutheran college, a Roman Catholic hospital, three licensed grain elevators, and two banks. Pop. (1951) 4,000.

MELVILLE ISLAND, an island off the northwest coast of Northern Territory, Australia, at the entrance to Van Diemen Gulf, is 65 miles long and 40 miles wide; area about 2,400 square miles. It is hilly and densely wooded, especially with several species of eucalyptus. The earliest British settlement was made in 1824.

MELVILLE ISLAND, an island of Canada, in Franklin District, Northwest Territories, in the Arctic Ocean. It is the largest of the Parry Islands (q.v.). The island, 200 miles long and from 30 to 130 miles wide, is generally hilly, with several ice-covered areas in the interior.

MELVILLE PENINSULA, North America, a northeastern projection of Keewatin in the Northwest Territories of Canada, about 400 miles north of Hudson Bay; bounded on the north by Fury and Hecla Strait and on the east by Foxe Basin, it is about 250 miles long by about 100 miles broad. At the base of the peninsula is Repulse Bay trading post.

MEMBRANE, *in anatomy and physiology,* a thin sheet-like tissue, more or less elastic, varying in structure and vital properties. Membranes absorb or secrete fluids, connect certain parts of the body, separate, envelop or form certain organs or act as partitions between two fluids or gases, permitting them to mingle. Mucous membranes line the canals, cavities and hollow organs which communicate externally by different apertures on the skin; for example, the digestive, respiratory and genito-urinary tracts. These membranes are soft and velvety and have on their free surface cells for absorption or motion and in their substance follicles which secrete mucus for lubricating and other purposes. Such secretions are saliva, gastric juice and pancreatic juice. Serous membranes, such as the peritoneum, pleura, the unicæ vaginales and pericardium, facilitate the motion of the organs they envelop (abdominal digestive organs, the lungs and heart) by reason of the serum they secrete, and also maintain the shape of these organs. Allied to the serous membranes are the synovial membranes lining movable joints. By reason of their smoothness and by aid of their lubricating serum the ends of bones move readily upon one another. Fibrous membranes (for example, periosteum, dura mater and perimysium), not moistened by any particular fluid, augment the solidity of organs they envelop, retain them in position, favor their motion and form canals and rings for the passage of different organs. The membranes which envelop the brain and are extended to cover the spinal cord are called meninges. (See MENINGITIS.) The membranes enclosing the fetus are called the placenta. Other special membranes are Descemet's membrane, which is the fourth layer of the cornea of the eye, and Bowman's membrane, which is the second.

MEMBRE, mäN-brā', **Zenobius,** French missionary in America: b. Bapaume, France, 1645; d. Fort Saint Louis, Tex., 1687. He became a member of the Récollet Order; was sent as a missionary to Canada in 1675; accompanied La Salle in his western expedition; was with Tonti at Crèvecœur, where he helped bring about peace between the Iroquois and the Illinois; in 1682 went down the Mississippi with La Salle, and in the same year returned to France. For a time he was warden of a convent in his birthplace. But in 1684 he set out again with La Salle for the mouth of the Mississippi. He was left by La Salle at Fort Saint Louis and there massacred by the Indians. He wrote a description of his trip down the Mississippi, which was incorporated by his cousin, Christian le Clerq, into his *Etablissement de la Foi dans la Nouvelle France* (1691), and which was later unscrupulously copied by Hennepin (q.v.). This narrative has sometimes been attributed to La Salle.

MEMEL, mā'mĕl (Lithuanian KLAIPEDA; German MEMELGEBEIT or MEMELLAND), territory, on the east coast of the Baltic Sea, 70 miles north by east of Königsberg. It belonged to Germany but under the Treaty of Versailles was ceded to Lithuania Feb. 16, 1923. It was almost wholly destroyed by fire in 1854, and was rebuilt in modern style. It has a large harbor, and exports from Lithuania and Russia great quantities of timber, also flax and linseed, coal, manure, grain and herring; has also manufactures of brandy, soap and chemicals, sawmills, iron foundries, breweries and ship-building yards. Memel was founded in 1252 by the Livonian order, who gave it to the Teutonic Knights, by whom it was fortified in 1404. It suffered severely in the Lithuanian wars (13th and 15th centuries). Here in 1807 Frederick William III of Prussia took refuge and a treaty with England was signed. It was seized by Russia in 1812 and 1914, but on each occasion that country was obliged to give it up. It was surrendered to Germany by Lithuania on March 22, 1939, and was held until taken by the Russian armies in January 1945. It was then made a part of Lithuania under Russian control. Pop. (1939) 147,569.

MEMLING, mĕm'lĭng, or **MEMLINC, Hans,** Flemish painter: b. Mainz, about 1430; d. Bruges, 1495. He settled at Bruges 1478, of which town he was a prosperous citizen until his death. While all that is handed down of his biography is apocryphal, it is evident, from his works, that he was an imitator of Roger Van der Weyden, although he avoided the harshness and ungraceful drawing of that artist's style. He stood alone among the Flemish painters of his day in the religious tenderness of his pictures, their life-like expression, their exquisite coloring and modeling. His chief works are to be found in St. John's Hospital, Bruges, namely, the altarpiece, *Marriage of Saint Catherine* (1479); *Portrait of Maria Moreel as Sybilla Persica* (1480), and the 14 scenes illustrating the legend of Saint Ursula and the 11,000 Virgins of Cologne (1589). In the Academy of Bruges is a triptych of his in the central panel of which are Saints Christopher, Maurus and Aegidius, and on the wings, Burgomaster Moreel (who offered the picture) with his family. In the Royal Gallery at Turin is his *Seven Dolors of Mary*—a passion picture; in the Pinakothek at Munich a compan-

ion picture, 'The Seven Joys of Mary.' Consult Michiels, 'Memlinc, sa Vie et ses Œuvres' (1883); Wauters, 'Sept Etudes pour Servir à l'Histoire de Hans Memlinc' (1894).

MEMMI, měm'mē, **Simone.** See MARTINI, SIMONE.

MEMMINGER, měm'mĭn-jĕr, **Christopher Gustavus,** American politician, secretary of Treasury in the Confederate government: b. Württemberg, Germany, 17 Jan. 1803; d. 7 March 1888. He was brought to America in infancy, and was educated at South Carolina College. He studied law; began to practise in Charleston in 1825; entered politics as a leader of the Union party; attacked the States' Rights party in a satire called 'The Book of Nullification' (1832); reformed the public school system of the State, and for 20 years was in the State legislature, much of the time acting as head of the finance committee. In 1859, after John Brown's raid, he was commissioned by South Carolina to consult with other delegates in Virginia as to the best method of warding off attacks of Abolitionists. From the formation of the Confederacy until June 1864 he was Secretary of Treasury, and his mistaken policy in that office did much to ruin the Confederacy financially.

MEMNON, in Greek mythology, the son of Eos (Dawn), an Ethiopian prince, nephew of Priam, for whom he fought at Troy. After he had killed Antilochus he was defeated by Achilles. The post-Homeric legend adds that his mother wept bitterly for him, even after he had been made immortal. Memnon's kingdom was localized on the west bank of the Nile, and one of the colossal statues of Amenhotep III, as early as the 1st century A.D., became connected with the myth. It was said to portray Memnon, and the musical note emitted when the sun's rays struck the statue in the early morning (probably due to the action of sudden heat on the chilled damp stone) were explained as Memnon's greeting to his mother. The statue, rehabilitated by Severus, is still sonorous. The name Memnonium was applied in the Ptolemaic period not only to the west bank of the Nile, as «Memnon's land,» but to a temple near Abydus, excavated by Mariette in 1859, which contains the famous «gallery of kings.» This has a list of 76 Egyptian kings, and dates from the time of Seti I and his son, Rameses II. This Memnonium contains many other important sculptured documents.

MEMOIRS OF CARLO GOLDONI ('Mémoires de Carlo Goldoni'). This work is celebrated among the many of this class in literature, and yet, in a general way, is comparatively little known. The 'Memoirs' were written in French, when Goldoni was 80 years old, and first appeared in Paris in 1787 (3 vols.). An excellent edition, reproducing them entire and accurately, was published on the second centenary of the author's birth 1907, by the Florentine firm Barbèra, edited with Italian notes by Guido Mazzoni. It was in 1760, a year before Goldoni was called to Paris, that he conceived, as he states in the preface to the 'Memoirs,' the idea of an autobiography. On seeing that the first Florentine edition of his plays had become the subject of universal pillage, no less than 15 editions having been published without his knowledge and very incorrectly, he resolved to publish a second edition at his own expense and insert in each volume a part of his life, imagining that in this way the history of his person and his plays might be completed together. Moreover, it occurred to him that possibly a collection of his works might some day be discovered in a corner of some old library and awaken curiosity to know something about the writer who undertook to reform the Italian theatre and wrote 150 comedies of character and intrigue. But as the years rolled on and the work which was to extend to 30 volumes and become completed in eight years had only reached the seventeenth volume, Goldoni realized that his project would not be completed during his life. So setting to work six years before his death, abridging and translating into French the contents of the historical prefaces of his 17 volumes of the Venice edition of the plays which related mostly his early life, and continuing with an account of the reformation of the Italian theatre, due largely to the author's theatrical genius, he completed the first part of the 'Memoirs.' The second part gives an account of the composing, construction and outcome of his many plays, together with the criticism of them and rivalry excited by them. The third and final part of the 'Memoirs' relates the author's personal experiences in France from 1762 to their close in 1787.

The 'Memoirs' of Goldoni have been called his most amusing comedy and pronounced by no less a literary light than Gibbon, «more truly dramatic than his Italian Comedies.» They have been the subject of admiration of some of the most distinguished of litterateurs not only in Italy but in England, France and Germany, is proven by such testimony as that of Byron, Voltaire and Goethe. But to appreciate and enjoy Goldoni's entertaining personal reminiscences, no such extraordinary literary talent is necessary,— far from it, for the average reader can hardly fail to get enjoyment from them, especially if he be at all interested in 18th century life in Italy. As a faithful picture of the life of this period, especially the life of the humbler classes, the 'Memoirs' of Goldoni rival his plays and are unexcelled. The parts that relate to Venice, Chioggia and to life in the Italian cities where Goldoni had his many and varied youthful experiences have that genuine ring found in his best plays in Italian dialect depicting life among the common people. The portions relating to the author's life in France, although far from lacking in interest, have not the charm that the parts of the 'Memoirs' have which relate to Italy. There is an English translation of the 'Memoirs' by John Black (2 vols., London 1827). The same, abridged and edited, together with a luminous introduction by William Dean Howells (Boston 1877). For everything concerning Goldoni and his works, consult H. C. Chatfield-Taylor's masterly work 'Goldoni, a Biography' (New York 1913).

JAMES GEDDES, JR.

MEMORIAL ARCH, an arch usually built across an avenue or street, or at an entrance to a park, garden or other public place, to commemorate some person or event. The

Washington Arch in Washington Square, New York City, is a well-known American example of the memorial arch. It is built of marble and is adorned with elaborately carved figures.

MEMORIAL ARCHITECTURE. See SEPULCHRAL ARCHITECTURE.

MEMORIAL DAY. See DECORATION DAY.

MEMORY IN ANIMALS is to be studied in the light of comparative psychology, as between the human and the animal mind. To one class of thinkers this difference seems only one of degree; the mind of the animal to them is of the same nature as that of man, but is less developed by reason of limited experience, lack of stimulus because of comparatively small means of intercommunication of ideas, and general inferiority in complexity of brain structure. To another class of thinkers there is an essential difference — a permanent gulf between the mental processes and powers of brute and human beings. Memory is one of the most important attributes of mind and must vary with varying mental abilities. Thus it is hardly, if at all, perceivable in animals of low organization, but is more and more recognizable as we ascend the scale of animal organization, until at the top its operation is clearly visible. In studying it as regards animals we are met, however, with this initial and constant difficulty, that while we are able not only to question ourselves and report what we find for comparison with and discussion of the self-examination by other men, we cannot see into an animal's mind and must judge of its processes by their outward signs. Thus we may assure each other that we possess imagination, which is a high function of memory; but how are we to discover whether an animal indulges itself in such a mental exercise? When a horse goes slowly and with hanging head on an outward journey but becomes instantly animated and brisk in his gait when he is turned toward home, is that because he pictures in his mind the comfortable stable and good food awaiting him? If so, is that not an example of imagination? It has been customary to attribute all such acts as nest-building and the like to "instinct," but innumerable examples of both faulty and beneficial work of this kind discourage faith in so simple a solution; and when a bee ingeniously stays a falling comb by a new brace or guy of wax, or a beaver overcomes a change in his pond by altering the direction of his dam or by building another in a new place, must these creatures not exercise imagination in order to plan and carry out the new way of meeting an unexpected difficulty? Each is applying his experience, recalled by memory, in the way he pictures (must picture) to himself the result of what he purposes to do, or he could not carry out his intention. That the animals we know best, horses, dogs, cats and so forth, have a very retentive memory, at least in certain directions, every one knows. The theory of many students of the matter is that this is purely "associative," that something they see or smell or hear recalls a group of facts connected with it; and that it is impossible for them to recall this group without such a concrete suggestion. Much evidence may be produced throwing doubt on this limitation of their power.

ERNEST INGERSOLL.

MEMORY AND ITS DISORDERS. Locke has defined memory as "the power the mind has to revive perceptions which it once had, with the additional perception that it has had them before." Ribot distinguishes three functions of memory: (1) the preservation of certain states, (2) their reproduction and (3) their recognition. In view of the fact that the collection of gray matter in the cerebro-spinal axis below the cortex is capable of storing impressions and that probably all parts of the sensory nervous system are concerned in mind action and in memory, it will be necessary to speak not merely of memory but of memories, in the sense of reproductions of like sense quality with the original impressions. Modern psychology accepts the concept of unconscious memory, which would imply that all impressions upon all sense organs are permanently retained in the organism. In this case the question is not so much how we remember as why we forget. An answer to this question has been found by the present day analytical psychology of the unconscious. Up to the time of the acceptance of these views the determinants of memory were considered to be frequency of repetition of the stimulus, or its intensity, or its interest or a combination of these factors. From a purely mechanical point of view memory is interpretable as a result of a biochemical phenomenon. The sensory nerve cells, being acted on by certain stimuli, whether of touch, taste, hearing or sight, undergo certain molecular changes. Repetition of similar impulses induces similar reactions and a habitual response in the affected cells results. A line of least resistance is established and in these habitual responses the germ of the idea of memory is to be found.

From this point of view the nerve-cells retain something as a result of a previous experience, and the repetition of the stimulus finds the cells in a receptive state. Continued repetition of the stimuli constitutes a memory, and in this sense the training of a certain mechanism has bound up in it this mechanical theory of memory. Thus a muscular effort, as in tennis, or skating, or piano-playing, becomes by repetition remembered in automatic action, frequently without consciousness. It is the usual rule that many muscular acts which in their acquisition have called for conscious memories soon become automatic, and the effort no longer rises into consciousness, perhaps because of its diminished intensity. A similar point of view may be held for sound-impressions, for taste, for touch, for sight, in each individual case a different series of nerve-cells and nerve-fibres being involved. Thus the memory for a poem may mean a habit-response to a series of sight or sound impressions, or of the muscular memories of the speech mechanism that has learned to repeat the phrases. The actor who automatically says his lines, often not conscious of what he is saying, the pianist who mechanically plays, or the golfer who unconsciously drives true, all show the same class of memory adaptations, involving different nervous chains.

There are thus not only a visual memory, but an auditory memory, or memory for sounds, a gustatory memory for tastes, an olfactory for smells, and special memories for the other special classes of sensation. Older psychology

was concerned with the question as to the fidelity and longevity of these special memories or types of memory, as related to each other, and with the discovery of laws according to which they might be revived. (See MNEMONICS). But with the introduction of the unconscious as a dynamic factor, the recalling of a previous experience is explained on a new principle. Memories are thus seen in the form of ideas to be reproduced into consciousness by virtue of forces which are mainly unconscious, and over which consciousness has only an indirect control, and the study of memory as such retires to an importance secondary to the study of the causes why some things tend to be remembered and others tend to be forgotten. This trend or tendency on the one hand to be forgotten or on the other to be remembered is now known to be determined by the unconscious wish, a force which is termed the *libido* and which is the prime mover, although uniformly unrecognized, of all the activities of the ego, both conscious and unconscious.

The mental mechanisms by which the unconscious pervades and indirectly controls all the conscious expressions, whether activities or thoughts, will be discussed under the title PSYCHOANALYSIS. In connection with memory it is necessary here only to point out that what we remember is only the residua after the work accomplished by the processes of repression, during which most of our former experiences are forgotten. On the fundamental principle that what is unpleasant in experience is from earliest infancy rejected by the individual ego, and regarded as if it did not exist, we may regard the ego as similarly rejecting or repressing the memories of impressions associated with the unpleasant or painful incidents. This explains why some things are forgotten and others are remembered. The unconscious, which functions solely on the principle of accepting or striving for the pleasurable and rejecting or repressing the painful, therefore furnishes the motive force for injecting certain ideas into consciousness, and restraining other ideas from entering. On this fact depends the further phenomenon that the dynamic factor called the libido, in becoming attached to certain ideas which are thrust out of consciousness, may be *converted* and its force applied to vegetative functions of the body producing in many cases certain forms of disease. See MEDICINE AND PSYCHIATRY.

Memory, however, does not depend on repetition of stimulus alone. There are variations in intensity and duration of stimuli, modifications in plasticity of the nerve-cells themselves, the quality of attention, and above all the native individual character of health of the nerve-tissue itself—all of which factors enter into the everyday variations in memory that are familiar to all. The fixity and enduring quality of the memories of childhood are proverbial, and are due to the great plasticity of the youthful nerve-cells, as well as to the intensity of the early pictures. That one person should have a good visual memory and a poor auditory memory, and vice-versa, must naturally be interpreted as due to variations in individual capacity. Modern pedagogy has slowly recognized these variations, and the greater prominence given to play, and to methods of precision, be they manual, lingual, auditorial or visual, and less to distinctly formal methods of memorizing as a purely visual process from a printed page, may be regarded as evidence of this wider recognition that memory should be a generalized function, and not a pedantic cramming of any sort. A well-trained muscular system may be of far greater use to a man than any of his acquired knowledge. It is impossible to train certain children to do certain things, whereas in other directions training may result in great proficiency.

Disorders of Memory.— The classifications of disorders of memory into those of defect and those of excess is based on the old psychology which laid most of the defects to lesions in the cortex of the brain. The newer view, while admitting the loss of memory evinced by the physical defect in the brain or nerve substance, admits also a purely functional deficiency in various memories which is determined by the unconscious wish and is entirely independent of any organic lesion or defect. It is agreed by most psychologists that the native retentiveness in any given individual does not itself alter, although there may be in one individual a finer nerve and brain structure than in another, enabling one to perceive and therefore retain finer distinctions. But the ability to recall at will, which is the essential quality of a good memory in the ordinary sense, is dependent solely upon the proper alignment of the unconscious wish with the desires of the conscious life, which are determined by the social environment of the individual.

The general term for deficiency or loss of memory is amnesia, although this term fails to express the various distortions of memory, the illusions or slight absences; and there are no technical words to distinguish temporary or permanent, periodic or progressive stages of the amnesic process. Inasmuch as memory is not one thing, but a great assemblage of processes which reflect a vast variety of psychological functions, situated not in the brain alone, but almost anywhere in the nervous system, a "defect in memory," as defined by Jastrow, "is an expression of the incapacity of a group (or of certain groups) of centres to exercise their normal functions; or a tendency which they show to functionate in an abnormal manner." Defects of memory may be general or special. General defects may be due to an incapacity on the part of nervous centres to establish residua. This type is found in those people who never remember what they see, and, notwithstanding frequent repetition of an act, never acquire proficiency in it. Occasionally a reverse general condition is manifest wherein the power of memory is unduly exalted and impressions of past experience reappear with unusual brilliancy. Such states are known in fevers, in intoxications of various kinds as of alcohol, opium, etc., and in the hypnotic trance. Special defects may arise in which particular isolated experiences are cut out of the mind. Thus alcoholic amnesia, that may forget even a committed crime, is an illustration. Somnambulism and other hysterical states are characterized by defects of this special type. Another form of defect is observed when associated memory-groups are blotted out, as in the special disorder aphasia. (See APHASIA; SPEECH, DEFECTS OF). Memory may be falsely localized in time, or in order; imaginary additions to

real events may be present; or illusory remembrances of what has never been experienced occur. Disorders of memory are never primary conditions but depend upon either the physical nerve or brain defect for which there must always be a corresponding deficiency in memory or upon the psychological conditions referred to above, where the specific memories are inhibited by associations with unpleasant or painful situations. Through the technique of psychoanalysis a great amount of forgotten material can be restored to memory by means of living over again the situations in which occurred the events responsible for the apparent obliteration of the memory.

Psychologically considered, memory defects may occur either in the storing or retentive part of the nerve-cells, or they may involve the much more complicated and associated process of reproduction of the retained images. Both processes may be involved at the same time. In imbecility, idiocy, and dementia, a born or acquired loss of retentive power is present. In pianists—for example, Ignace Paderewski—or chess players—Paul Morphy, Harry Pillsbury, a state of localized hyperamnesia is present. This group would include all such prodigies. Occasionally one sees these two groups represented in one individual, as in an imbecile who has great power for mathematical calculation. A case of this kind proves that the old assumption of closely localized memory-centers is false. Memory may be said to reside in all parts of the sensory nervous system. In another group the ordinary amnesias may be placed. These vary with each individual and depend largely on the healthy tone of the nervous system.

A third group would include the paramnesias, or illusions of memory. In this condition: (1) there is a loss of distinction between memory of things which really did happen and an imagination of things which never did or could. The so-called "constitutional liar" is an example of this inability to distinguish between real and imaginary, and many types of insane persons are similarly affected in an extreme degree.

The reverse of taking an imagination for a real thing is (2) taking a real thing experienced for the first time as a memory of something experienced before—thought of having seen, heard or felt "just that same thing before," also called "deja vue." Such a feeling has nothing to do with native retentiveness, but only with the "feeling of familiarity," which is essentially the presence of an organic sensation which is absent in the simple paramnesia. In some insanities this form of double memory is very prominent and leads to the belief on the part of the person so affected that he is prophesying when he is only recalling what he experienced before.

(3) There is also an associated paramnesia in which things actually experienced suggest ideas falsely taken as memories of other things never experienced. This condition is seen in children and often leads to false testimony. It is also responsible for most "presentiments" or alleged antecedent knowledge of what has happened. Examples of such memories of the actually nonexistent are seen in the stories of faith cures, where all the healing is that of ills that never really existed, save as associated false memories. On these false memories is erected much of the complicated structure of spiritualism, second sight and other similar phenomena.

SMITH ELY JELLIFFE, M.D.

Bibliography.—Waldfogel, S., *Frequency and Affective Character of Childhood Memories* (Washington, D.C., 1948); Bergson, H. L., *Matter and Memory*, 6th impression (New York 1950); Rapaport, D., *Emotions and Memory*, 2d ed. (New York 1950).

MEMPHIS, měm'fĭs, an ancient city, Egypt (modern MIT RAHINA), near the apex of the Nile Delta, 14 miles south of Cairo, according to Herodotus, founded by Menes, the first king of Egypt. It was a large, rich and splendid city, and the second capital of Egypt. After the fall of Thebes it became the sole capital. Among its buildings the temples of Ptah, Osiris, and Serapeum, and its palaces were described as remarkable. At the time of the conquest of Egypt by Cambyses (524 B.C.) it was the chief commercial center of the country and was connected by canals with the Lakes of Moeris and Mareotis. With the rise of Alexandria the importance of Memphis declined, and it was finally destroyed by the Arabs in the 7th century. In Strabo's time (20 A.D.) it was, in population and size, next to Alexandria; in biblical history it is mentioned as Noph and Moph.

The name Memphis is a corruption of Mennofer, "good abode." Edrisi, in the 12th century, describes its remains as extant in his time. Among the works specified by him are a monolithic temple of granite 13½ feet high, 12 long and 7 broad, entirely covered within and without with inscriptions, and statues of great beauty and dimensions, one of which was 45 feet high, of a single block of red granite. These ruins then extended about nine miles in every direction, but the destruction has since been so great, chiefly for the construction of Fostat, an Arabic city on the opposite bank of the Nile, that although Pococke and Bruce fixed upon the village of Mitrahineh as the site (where prone on a mound are two colossal statues of Rameses II), this was not accurately ascertained until the French expedition to Egypt, when the discoveries of numerous heaps of rubbish, of blocks of granite covered with hieroglyphics and sculpture, and of colossal fragments scattered over a space of three leagues in circumference, decided the matter. The views of the great temple of Ptah, the palace of Apis, the sepulcher of the Apis bulls, portions of the White Wall and of pyramids have been identified.

MEMPHIS, city, Missouri, and Scotland County seat; altitude 796 feet; 45 miles west of Keokuk, Iowa; on the Chicago, Burlington and Quincy Railroad. The surrounding area is agricultural, and the city is a trade center for its own and adjoining counties, and a shipping point for farm and dairy products, and livestock. There are bituminous coal fields within the county. Pop. (1940) 1,935; (1950) 2,035.

MEMPHIS, city, Tennessee, county seat of Shelby County, altitude 274 feet; area 116.41 square miles, on the Mississippi River, is the largest city in Tennessee and the most important commercial center and distributing point between New Orleans and Saint Louis.

Communications.—Memphis has nine line railroad systems operating 17 divergent rail lines and consisting of the Illinois Central; Frisco Lines; Louisville and Nashville; Nashville, Chattanooga and Saint Louis; Southern Railway;

Missouri Pacific Lines; Rock Island; Gulf, Mobile and Ohio; and the Cotton Belt. Two railroad bridges span the Mississippi River at this point. One of these is a combined rail and highway bridge—the only toll-free bridge spanning the river between Saint Louis and New Orleans. Memphis is located on thirteen federal highways. Nine bus lines provide intercity highway transport between Memphis and other cities. Barge line transportation on the Mississippi reaches all river ports and provides an outlet for export trade through the port of New Orleans. The Federal Barge Line operates between Minnesota and the Gulf, while the Mississippi Valley Barge Line provides through service from Saint Louis and Cincinnati to Memphis and New Orleans. Service to the Pittsburgh area via the Ohio River is provided by the American Barge Line and the Union Barge Line.

Memphis has airport facilities sufficient to accommodate the largest flying ships under all weather conditions. There are 13 air lines. Service to the Atlantic and Pacific coasts and to the Great Lakes and Gulf areas is now provided in addition to service to the Florida Peninsula.

The city has six radio broadcasting stations.

Economic Resources and Development.—Memphis is located in the center of and serves the most rapidly developing agricultural section of the country. It is the commercial capital of the Mid-South area which embodies Southeast Missouri, Eastern Arkansas, Western Kentucky, and Tennessee, Northeast Alabama and the northern half of Mississippi. The center of cotton production is some 60 miles south of Memphis. This vast hinterland, some 200 by 300 miles in area, produces cotton, corn, rice, wheat, tobacco, soy beans, dairy products, fruits and vegetables. Considerable impetus has been given to livestock raising in recent years. Within this area are many natural resources from which are procured many diverse mineral products including coal, oil, natural gas, ball and kaolin clays, as well as stone and marble.

Memphis is the world's largest hardwood lumber market. Hundreds of square miles of hardwood forests lie in the Memphis area, and strict conservation practices assure the industry's supply.

By reason of its location on the Inland Waterways System, the cost of transportation on imports is very low. Memphis handles over 300,000 tons of steel annually. The city has over 700 plants engaged in manufacture, and is the center of a $2,500,000,000 annual market in wholesale and retail trade. Principal among these are automobiles, auto tires and tubes, auto bodies, furniture of many types, plywood and veneer, flooring, lumber, toys, mixed feeds, cosmetics, perfumes, toilet goods, food products, beverages, medicines, pharmaceuticals, batteries, piston rings, structural steel, automobile lifts, brick, roofing, asphalt products, meats, bakery products, bags, soap, mattresses, lubricants, tool handles, golf club shafts and heads, lard, paints, electric signs, ammunition, shuttleblocks, pulp for viscose rayon, cottonwood oil, railroad forgings, railroad brake shoes, sheet metal products, iron and steel castings and many other commodities. The city controls a trade area 71,326 square miles. Memphis has some of the strongest strictly wholesale firms in the country in dry goods, hardware, drugs, mill supplies, groceries, electrical products, and agricultural implements. Over 600 nationally-known manufacturers and wholesalers maintain their own warehouses or sales offices in Memphis. The city also has five large department stores and a mail-order house.

In addition to a branch of the Federal Reserve Bank, there are 6 banks and trust companies in the city. The total resources of these institutions (1949) was $492,672,439.

There are two daily newspapers, one daily and Sunday paper, and one weekly paper.

Public Improvements.—In recent years many improvements have been effected. These include great housing projects and the elimination of slum areas, the erection of Crump Stadium with a seating capacity of 25,000, Riverside Drive along the banks of the Mississippi, a public grain elevator, the elimination of grade crossings, etc. A new pumping station has doubled the city's water capacity. Buses have replaced the more cumbersome trolleys on a great part of the more important transit lines and new routes have been added. In 1939 Memphis completed negotiations for the purchase of the Memphis Power and Light Company, and immediately TVA power was brought to the entire city and power rates have been reduced an average of 37.9 per cent.

The new Memphis and Arkansas Bridge, a gigantic project, was opened to traffic in January 1950. It is a four-lane highway bridge.

A valuable addition to industrial Memphis will be the Tennessee Chute Project, on which construction was started in 1948. This $18,000,000 project will provide a dam that will connect a large island in the river, just south of Memphis, to the mainland. This will give Memphis a deep, still-water harbor and 9,000 acres for industrial development on the new waterfront.

Port Facilities.—Memphis has a total of 7.88 miles of waterfront on the Mississippi and Wolf rivers. Memphis has municipally owned river terminals, including a package car terminal, carload terminal and river and rail grain elevators.

Civic Conditions.—The city is well laid out, and its further development is guided by a City Planning Commission. The wide, well-shaded and well-paved streets, the fine public and private buildings, the parks with numerous large trees, all make the city most attractive. Shelby County, in which Memphis is located, has 3,200 miles of paved and improved roads.

Memphis has 425 churches representing 28 denominations. Its superior educational advantages include the schools of pharmacy, dentistry and medicine of the University of Tennessee, Memphis State College, Southwestern University, the William R. Moore School of Technology, and the LeMoyne College for Negroes, University of Memphis Law School, Southern University College of Law, Southern College of Optometry, and Siena College. Its college preparatory schools include Christian Brothers College and St. Agnes Academy. Musical education is provided through the medium of the Memphis College of Music, the Memphis Conservatory of Music and numerous private studios. Memphis has 70 public schools including 11 senior high schools and nine junior high institutions. There are nine parochial schools, with an enrollment of 6,800. The public school enrollment is 46,947 pupils. Memphis has 10 public libraries, with a total of 264,864 volumes. Foremost of these are the Cossitt Library and the Goodwyn Institute Library, the latter being an endowed institution with an auditorium and lyceum lecture course.

Memphis is one of the foremost hospital cen-

ters of the South, having a total of 21 hospitals with 10,007 beds. Notable among these with Class A rating of the American Hospital Association, may be mentioned the Baptist Memorial, John Gaston Memorial Hospital, Methodist, St. Joseph's Crippled Adults and Crippled Children's hospitals. In addition to these, a United States Marine Hospital is located here as well as a United States Veterans' Hospital Facility No. 88. Memphis is provided with numerous clinics and private hospital institutions, and there are four sanitariums located just outside the city limits.

Local welfare institutions include the Anne Brinkley Home for Girls, the Mary Galloway Home for Aged Women, the Sunshine Home for Aged Men, the Tennessee Home for Incurables, and the Young Women's Christian Association and Young Men's Christian Association organizations. In addition, the city has three white orphanages and one colored orphanage.

The city has a municipal auditorium. The leading downtown clubs are the Catholic Club and the Rex Club. Other clubs are the University Club and the Nineteenth Century Club, the latter being a club for women. There are several country clubs, private and public golf courses operated by the Memphis Park Commission.

The city has been known as one of the cleanest cities in the United States for many years and has won national awards for its health and welfare work, and its noise-abatement campaigns.

Parks, Public Buildings, etc.—There are 41 improved parks with a total area of 1,421.58 acres. Two of the major parks are connected by a 12-mile boulevard or parkway encircling the city. The largest park is Riverside Park on the east side of the Mississippi River, just south of the city, containing 427 acres, much of which is left in its state of natural beauty. Next in point of size is Overton Park, one of the most beautiful parks of the South, located in the northeastern portion of the city and containing 355 acres. Within its boundaries are located the Memphis Zoological Garden, one of the finest in the nation, the Brooks Memorial Art Gallery, and the Open Air Theatre where some of the finest musical productions are performed each summer season. DeSoto Park is named for Hernando DeSoto, Spanish explorer. In this park near a great Indian mound, is a memorial, consisting of a ledge of rough granite with bronze tablets thereon, containing this inscription: "Near this spot Hernando De Soto discovered the Mississippi River in May 1541."

Russwood Park is the home of Memphis' Southern League baseball team, and E. H. Crump Stadium is the scene of outstanding college football games.

Recreational facilities are provided through 29 playgrounds, three swimming pools, seven community centers, 10 golf courses, 19 wading pools, 60 tennis courts, an athletic building for indoor sports, two stadiums and 12 baseball diamonds. The Park Commission has 100 persons on its recreational and playground staff. Of the 12 baseball diamonds, seven are equipped for night softball games, attracting approximately 300,000 per year.

Memphis has many fine buildings including the Custom House and Federal Building, the Shelby County Court House, the Criminal Courts Building and the Central Police Station, all of which are the finest examples of architecture. The city enjoys the distinction of having the largest artesian water system in the world, obtaining its city supply from an inexhaustible vein which runs as far as the Cumberland mountains in Tennessee. The waterworks are municipally owned and operated, with a capacity of 105,000,000 gallons per day and with 906 miles of mains.

Modern sanitation methods obtain in its sewer system and $2,000,000 was expended in 1938 for improvements. Shelby County, in which Memphis is located, has one of the finest county hospitals in the United States which provides care for the indigent, sick and aged. Its Penal Farm is a modern institution in point of splendid facilities and methods employed. The Pink Palace Museum houses an attractive and extensive exhibit of mechanical arts. Memphis is the home of the Cotton Carnival, a week-long festival held each May, when the city honors "King Cotton" and his colorful court.

The Memphis Little Theatre presents a season of plays each winter, and the Memphis Auditorium books many famous persons from the theatrical world.

In writing of Memphis, one must not overlook Beale Street (or Avenue), where W. C. Handy wrote his immortal "Blues" songs. Modern Beale Street is now a far cry from the sinful street of the past—today it is a well-behaved, neon-lighted shopping district for Memphis' Negroes, but it is still a colorful and interesting street.

History.—The history of Memphis begins almost with the history of the United States. It was a landing and tenting place for the early explorers and missionaries. It was the home of the Chickasaw Indians, and the bluffs on which the city is located, 40 feet above high water and 80 feet above low water, have always been known as the Chickasaw Bluffs. Perhaps the first industry in America was established here in 1541 when DeSoto and his band of followers erected a shipyard for the construction of barges and piragues with which to cross the Mississippi River, then seven miles in width. In 1698 the French built forts on the site of what is now the city, and in 1794 the Spaniards erected forts at a time when Spain was claiming exclusive right to the lower Mississippi. Some of the foremost men in the United States owned lands in this vicinity and were interested in holding for their own country a right to free navigation on the Mississippi to the Gulf. Andrew Jackson, James Winchester and John Overton sent to Memphis in 1819 a small colony who established the first permanent settlement. In 1826 there were 500 persons in the settlement which was then incorporated as a town, and in 1849 a city charter was granted. The Union and Confederate forces tried to gain possession of the city at the beginning of the Civil War. On June 6, 1862 a Federal fleet under Commodore C. H. Davis conquered a Confederate fleet under Commodore J. E. Montgomery, thus placing Memphis in possession of the Union forces. General N. B. Forrest in command of Confederate forces entered the city in August 1864 and took several hundred prisoners. Memphis has always progressed commercially except during the Civil War, and when visited formerly by yellow fever epidemics. The great growth industrially has come within the last three decades. Its location has made the city a great railroad center; the surrounding forests made it a great industrial center; and the alluvial lands of the Saint Francis Basin, Yazoo Delta and the Valley of the Mississippi River will al-

ways make it a great commercial center. In 1855 yellow fever attacked the city, and again in 1867, 1873, 1878 and 1879. The epidemics of 1878 and 1879 so paralyzed the industries of the city that in 1879 Memphis was unable to liquidate the current indebtedness and the charter of the city was revoked. The former city was designated by the state legislature as "the taxing district of Shelby County." The control of the district was vested in a board of public works composed of five members, and a governing council composed of three commissioners. The council instituted the sewerage system, which practically eliminated the recurrence of yellow fever, improved civic conditions, liquidated the debts and in 1891 the place was reincorporated and again chartered as a city.

Population.—The growth of the city may be seen from the federal census reports. Pop. (1920) 162,351; (1930) 253,143; (1940) 292,942; (1950) 396,000. Only 1.5 per cent of Memphis' population is foreign born and 41.4 per cent is colored.

Consult Davis, J. D., *History of Memphis and the Old Times Papers* (Memphis 1873), most valuable for period prior to 1850; Williams, S. C., *Beginnings of West Tennessee, 1541–1841* (Johnson City 1930), objective; excellent background; Abernethy, T. P., *From Frontier to Plantation in Tennessee* (Chapel Hill 1932), best history, but ends in 1860; Hamer, P. M., *History of Tennessee*, 3 vols. (New York 1933), covers entire period; Capers, Jr., G. M., *The Biography of a River Town; Memphis: Its Heroic Age* (Chapel Hill 1939), excellent bibliography of primary and secondary sources, pages 269-279.

MEMPHIS (Tenn.), **Capture of.** At dusk June 5, 1862 the Union flotilla under command of Commodore C. H. Davis appeared near Memphis and anchored two miles above the city. The Confederate flotilla, Commodore J. E. Montgomery commanding, was lying at the Memphis levee. At daylight the Union fleet began to drop down toward the city, and the Confederates advanced to meet it. There were no troops protecting the city. The flotillas were composed of the following vessels:

Union	Guns	Confederate	Guns
Benton	16	Little Rebel	2
Louisville	13	Bragg	3
Carondelet	13	Beauregard	4
Cairo	13	Price	4
Saint Louis	13	Sumter	3
Queen of the West	ram	Lovell	4
Switzerland	ram	Thompson	4
Monarch	ram	Van Dorn	4
Lancaster	ram		28
	68		

Besides having more than twice the number of guns, the Union ordnance was much superior to that of the Confederates. The latter, however, made a desperate fight, which finally ended 10 miles below the city, with the result that the *Lovell, Beauregard* and *Thompson* were destroyed; and the *Little Rebel, Price, Sumter* and *Bragg* captured. The *Van Dorn* escaped. On the Union side only the *Queen of the West* was disabled.

Immediately after the fight the mayor, in reply to a summons to surrender, informed Commodore Davis that there were no troops with which to oppose him. The next morning detachments from troops under Col. C. N. Fitch, which accompanied the fleet, landed and took possession of the city.

General Grant arrived at Memphis June 23 and established the headquarters of the District of West Tennessee. He was recalled to Corinth July 15 and General Sherman was ordered to Memphis, reaching the city July 21. He restored the mayor and the city government, and made them responsible for civil order. He continued in command at Memphis until his forces left to joint General Grant in the final campaign for Vicksburg, having previously participated in the first move against that city.

The raid of Gen. N. B. Forrest, of Confederate cavalry fame, into Memphis occurred Aug. 21, 1864. The Union forces and commanding officers were completely surprised and barely escaped capture. Gen. C. C. Washburn, in command of the District of West Tennessee; Gen. R. P. Buckland of the District of Memphis, and Gen. S. A. Hurlbut were asleep in the city. General Forrest left the vicinity of Oxford August 18, with three brigades, making a forced march of nearly 100 miles. A strong detachment rode into the city at 4 o'clock in the morning, running over a regiment of 100-days men on picket, and capturing about 250 of them. This force divided into three and at once surrounded the quarters of the three officers named. Each, however, escaped.

MEMPHIS, city, Texas, in Hall County, altitude 2,067 feet, on the Fort Worth and Denver City Railroad, 85 miles southeast of Amarilla. Cotton processing is its principal industry. Pop. (1940) 3,869; (1950) 3,810.

MEMPHREMAGOG, mĕm-frē-mā'gŏg, **Lake,** in the southern part of the province of Quebec, Canada, extending into Orleans County, in Vermont. It is about 30 miles long, north and south, and from one to four miles wide. It is irregular in shape, and along its shores are several striking indentations, in some places low and in some other parts high and rocky. The land on the west shore is mountainous, the altitude of the highest points being about 2,800 feet. The outlet is the Magog River, which flows into the St. Francis River. Along the shore are a number of villages, and in summer a steamer plies daily on the lake, connecting the chief towns and villages.

MENA, mā'nä, **Juan de,** Spanish poet: b. Cordova, Spain, about 1411; d. Torrelaguna, 1456. He was educated at Salamanca and at Rome and afterward was appointed secretary and court historian to John II, king of Castile. His allegorical poems, *Coplas de los Siete Pecados Mortãles, Le Coronacion,* and *El Laberinto de Fortuna,* a poem founded on the *Divina Commedia* and published in the year 1496, all show the influence of Dante, for whom he held great respect and admiration. His collected works were published in 1528, entitled *Copilación de todas las obras de Juan de Mena.*

MENA, city, Arkansas, and Polk County seat; altitude 1,145 feet; 86 miles south of Fort Smith; on the Kansas City Southern Railroad. It is in a summer resort region of the Ouachita Mountains, is a shipping point for lumber, and the business center of a farm and dairy area raising truck crops, corn, peanuts, soybeans, berries and poultry. It has bottling works, flour mills, and manufactures of cream cheese, finished lumber. window sashes and doors, furniture,

wooden handles, slate roofing, headings and staves. Pop. (1940) 3,510; (1950) 4,445.

MENABREA, mā-nä-brâ'ä, Count **Luigi Federigo,** Italian soldier and statesman: b. Chambéry, in Savoy, Sept. 4, 1809; d. there, May 25, 1896. After completing a course in mathematics at the University of Turin and joining the engineers in the Sardinian army, he accepted the professorship of technical science at the military academy and at the University of Turin. Having been promoted to the rank of captain, he was used in the diplomatic corps for some time; was then elected deputy, serving both under the minister of war and the minister of the interior; and upon the outbreak of the war of Sardinia and France against Austria in 1859 he was appointed chief of the engineer corps. After Savoy was ceded to France, Menabrea was made a senator by Victor Emmanuel, and chief of the department of engineers, and as such planned the fortifications of Bologna, Piacenza and Pavia; in 1860 he was created a lieutenant-general, in that year laying siege to and after three months of fighting taking Gaeta. In 1861 he joined the Cabinet of Ricasoli as minister of marine; in 1862 he took over the portfolio of minister of public works. In 1866 he was Italian ambassador to the council which brought about the Treaty of Prague and ceded Venice to Italy. In 1867, when Rattazzi resigned, he formed a new ministry, himself becoming minister of foreign affairs. As premier he did much to place Italy in cordial relations with the outside world, and to settle internal dissensions, but his imprisonment of Garibaldi and the prevalent financial straits of the nation lost to him the confidence of the House of Deputies, and on Nov. 16, 1869 he resigned. In 1870 he became Italian ambassador at Vienna, was appointed to the same post at London in 1876 and in 1882 went to Paris, where he was stationed for 10 years.

The most important of his works are *Etudes sur la série de Lagrange* (1844–1847); *Le génie italien dans la campagne d'Ancone et de la Basse-Italie* (1866), and *République et Monarchie dans l'état actuel de la France* (1871).

MENAGE, mā-näzh', **Gilles,** French philologist and satirist: b. Angers, Aug. 15, 1613; d. Paris, July 23, 1692. After completing his early studies he became an advocate, practicing for some time at Paris, but, having conceived a profound disgust for that profession and all its adherents, he became an ecclesiastic, and for some time was a member of the household of the Cardinal de Retz, but subsequently took up his residence in the cloister of Notre Dame. A witty satire, entitled *Requéste des Dictionnaires,* published in 1638, and aimed at the *Dictionary* of the French Academy, prevented his becoming a member of that society.

His most important works are *Dictionnaire étymologique, ou Origines de la Langue Française* (1650–1694); *Origines de la Langue Italienne* (1669); *Miscellanea* (1652); *Poemata latina, gallica, graeca, et italica* (1656); *l'Anti-Baillet* (1690).

MENAGERIE, mē-näj'ĕr-ĭ, a collection of wild animals, exhibited in zoological gardens, in museums and by circus companies traveling from city to city. The term is now confined almost wholly to a collection exhibited in connection with a traveling circus, a permanent collection being styled a zoological park or "zoo." The menagerie of the typical circus is usually shown in a separate tent, so arranged that the public can make the round of the cages before taking their seats. The principal exhibits are usually elephants, a giraffe (when one is to be had), hippopotamus, rhinoceros, tapir, lions, tigers, bears, leopards (and others of the cat family), lynx, kangaroo, varieties of deer, monkeys, a few cages of snakes, and minor animals. See also Circus; Zoological Gardens.

MENAI STRAIT or **STRAITS,** mĕn'ī, the channel between Wales and Anglesey Island, is 14 miles long, and varies in width from 200 yards to ¾ mile. Menai Suspension Bridge and the celebrated Britannia Tubular Bridge connect Anglesey with the mainland. The tides and current are very strong at times, so that large vessels avoid the strait. See also Bridge.

MENAM, mă-näm', **MEINAM, MAE NAM, ME NAM, CHAO PHRAYA,** or **CHAO PHYA,** a chief river of Thailand, rising in the Laos country, and flowing generally southward to enter the Gulf of Siam below Bangkok. Its length is about 750 miles, although strictly the name applies only to the 160-mile lower course which begins at the junction of the Ping and Nan rivers. It is navigable for small craft. It is subject to periodical overflows on which the crops of the rice fields along its banks are dependent.

MENANDER, the name of two Greek writers:

Menander, the comic dramatist: b. Athens, 343? B.C.; d. there, ?291 B.C. He was the pupil of Theophrastus, himself the pupil and successor of Aristotle as head of the Peripatetics, and author of *Characteres,* a somewhat more literary and popular enlargement of some ruling ideas of the Nicomachaean Ethics; he was by such a teacher well trained for his dramatic vocation. He was, moreover, a friend of Epicurus from early life, and may thus have been imbued with that bonhommie which rendered him so genial an interpreter of manners. He wrote a hundred comedies which are distinguished from those of Aristophanes by their refinement, their freedom from personal and political virulence, and their graceful, sometimes beautiful, delineation of feminine character. He was, however, outrivaled in popular favor by his contemporary Philemon, whose ribaldry was irresistible to the Athenian playgoers. Only some fragments of his works survive in the original, the most important of these relics having come to light in Egypt (1898). He was, however, closely imitated by Plautus and Terence, and in the *Bacchides, Stichus* and *Poenulus* of the former, and the *Andria, Eunuchus, Heautontimorumenos* and *Adelphi* of the latter we have very good representatives of the Greek dramatist's method and spirit. A fine antique statue of Menander is to be seen in the Vatican.

Menander, a rhetorician who flourished in the latter half of the 3d century B.C. He has left the rhetorical treatise *De Encomiis,* and from his analyses of the orations of Demosthenes, most of the scholia on that orator have been compiled.

Consult (on Menander the dramatist), Guizot, *Ménandre* (1855); Horkel, *Lebensweisheit des Komikers Menander* (1857); (on Menander the rhetorician), Ritschl,

Der Rhetor Menander und die Scholien zu Demosthenes (1883).

MENARD, mā-nàr′, **Michel Branamour,** American pioneer: b. Laprairie, Lower Canada, Dec. 5, 1805; d. Galveston, Texas, Sept. 2, 1856. He was of French parentage, and after working some time for a Detroit fur-trading company entered the service of his uncle, also a fur trader, in Missouri. The Shawnees made him their chief, and he acquired great power among various Indian tribes. Soon after 1830 he went to Texas, where he continued fur-trading with the Indians, and also dealt with Mexicans. When the Texans revolted against Mexico he held the Indians in check and kept them from acting against the insurgents. As a member of the convention at which the Texans declared their independence, and afterward of the Congress of Texas, he exerted an influence in the formation of that state. The greater part of the site of Galveston was included in a purchase made by him in 1836, and of that city he, more than any other man, is to be considered the founder.

MENASHA, mē-năsh′ä, city, Wisconsin, and resort in Winnebago County; altitude 755 feet; on the navigable Fox River, at Lake Winnebago; 93 miles northwest of Milwaukee; on the Soo Line; Chicago and North Western; and Chicago, Milwaukee, St. Paul and Pacific railroads; immediately adjacent to Neenah with which it forms a continuous community. It has a tannery, printing plants, boiler works and manufactures of paper, paper products, and paper mill machinery, woodenware, pulleys, pumps and wire.

Menasha and Neenah were settled in 1843 on land ceded to the United States government by the Menominee Indians in 1836. Menasha received a charter to develop the water power and became the industrial center. Doty Island in the river belongs partly to each city; on the Menasha side, the site of Nicolet's landing in 1634 is marked. Pop. (1940) 10,481; (1950) 12,385.

MENCIUS, měn′shĭ-ŭs, the Latinized name of MENG-TSE or MENG-TZU, Chinese philosopher and recluse: b. province of Shan-Tung, c.372 B.C.; d. there, c.289 B.C. He was educated by his mother with such success that the approbation contained in the phrase "the mother of Meng" has become proverbial. Mencius was one of the greatest of the early Confucians. During his time the governments of China were oppressive, and Mencius for many years wandered about in search of a prince who would consent to govern in accordance with true and just principles. Failing to find any such, he retired to his former seclusion and spent the rest of his life in perfecting his system and training disciples. His works contain some enlightened views on man and society. He believed in the moral nature of man and had unbounded faith in the possibilities of progress under a good social and political system. He regarded all governments as from God, but at the same time he believed in the responsibility of rulers to their people and the people's right to depose or even put to death unworthy rulers. In a nation the people are the most important element, second comes the government and third the monarch. The aim of a government, according to him, should be the happiness and education of the people, and any ruler who was content to leave his subjects in ignorance and misery deserved to be deposed. The teachings of Mencius were written out by his disciples in dialogue form, under the title *Book of Mencius* which has been translated into Latin and into English.

MENCKEN, H(enry) L(ouis), American journalist, editor, essayist, and critic: b. Baltimore, Md., Sept. 12, 1880. After attending Baltimore Polytechnic Institute he entered newspaper work in Baltimore in 1899, was editor of the *Evening Herald* by 1906, and then joined the *Sun,* on whose staff he remained for the balance of his newspaper years. In 1908 he also became literary critic for *The Smart Set,* a magazine he served from 1914 to 1923 as part owner and joint editor with George Jean Nathan. From 1924 to the end of 1933 he was editor of the *American Mercury,* which he and Nathan founded.

Through his essays and criticism, H. L. Mencken exerted a powerful influence on American intellectuals during the decade following World War I. As literary critic he helped liberate American literature from academic, moralistic, and other restraints and assisted in bringing popular approval to such writers as Theodore Dreiser. As social critic he issued bristling attacks on America's vaunted traditions and satirized its delusions and weaknesses, in particular the imperfections of democracy. Everywhere he hammered at entrenched provincialism, complacency, cultural sterility, and vulgarity, with a style vigorous in its command of irony and invective and in the adeptness, vividness, and distinct freshness of its vocabulary.

Among Mencken's most influential volumes were *Notes on Democracy* (1926) and *Prejudices* (six series: 1919, 1920, 1922, 1924, 1926, 1927), while his most enduring work has probably been *The American Language* (1919; last of four revisions, 1936), with its two *Supplements* (1945, 1948) constituting a popular yet scholastically sound and careful discussion of the English language in the United States. Other Mencken works include *The Philosophy of Friedrich Nietzsche* (1908); *A Book of Prefaces* (1917); *Selected Prejudices* (1927); *Treatise on the Gods* (1930); *Chrestomathy* (1949); and his autobiographical trilogy: *Happy Days, 1880–1892* (1940), *Newspaper Days, 1897–1906* (1941), and *Heathen Days, 1890–1936* (1943).

MENDEANS. See NAZARENES.

MENDEL, měn′dĕl, **Gregor Johann,** abbot of Brünn, now known as the discoverer of the law named after him (see HEREDITY): b. Heinzendorf bei Adrau, Austrian Silesia, July 22, 1822; d. Brünn, Jan. 6, 1884. In 1843 he entered the Königinkloster, an Augustinian foundation in Altbrünn, as a novice; and was ordained priest in 1847. From 1851 to 1853 he studied natural science at Vienna; and, on his return to the cloister, taught in the Realschule. About 1869 he became abbot of Brünn; and later took part in the Ultramontane movement. It was in 1854 that he began those experiments, on *Pisum,* in the cloister gardens, that, after the lapse of half a century, have brought him posthumous fame. In 1865 he contributed his now memorable paper, *Versuche über Pflanzenhybriden,* to the Society of Naturalists of Brünn; and, in 1869, another, on *Hieracium* hybrids. After 1869 he seems to have discontinued his work in hybridizing, and died unrecognized by science. This seems inexplicable, as his researches were of a nature to commend them to his studious contemporaries, among them Darwin, who entirely missed his

contribution, even though the Brünn society exchanged with the Royal Society of London. But Mendel had the satisfaction of realizing that he had established a law in heredity as to the numerical ratios of the types developed in hybridizing — the grand fact for which we now prize his unobtrusive labors. His theories have given us the word Mendelism. He called himself a student of Kollar; and for some time he was president of the Brünn society. Since the verification of his experiments, simultaneously, in 1900, by De Vries, in Holland, Correns, in Germany, and Tschermak, in Austria, and of the translation of his paper appearing in the 'Journal of the Royal Horticultural Society of England' (1901), the literature has been full of "Mendel's Law." Consult Bateson, W., 'Mendel's Principles of Heredity' (Cambridge 1902).

MENDELEEV, myĕn-dyĭ-lyā'yĕf, **Dmitri Ivanovich,** Russian chemist: b. Tobolsk, Siberia, 7 Feb. 1834; d. St. Petersburg, 2 Feb. 1907. He studied at the Institute of Pedagogy, St. Petersburg, where he gave attention to natural science; in 1856 became docent at the University of Saint Petersburg; was at Heidelberg in 1859–61, where he published his monograph 'On the Capillarity of Gases,' soon followed by 'Organic Chemistry.' In 1863 he became professor of chemistry at the Saint Petersburg Institute of Technology, and in 1866 was appointed to a similar professorship in the University of Saint Petersburg. The results of his researches on the compression of gases, which he closely pursued from 1871 to 1875, were set forth in his work 'On the Elasticity of Gases.' He was commissioned in 1876 to report upon the petroleum industry in the Caucasus regions and in Pennsylvania. His 'Aqueous Solutions' (1886), a work on experimental chemistry, has taken its place among the most important contributions to that branch of science. In 1890 his 'Tariff Elucidated' presented the protectionist views of which he had already become a well-known advocate, and which, as a member of the Council of Commerce and Industries, he actively propagated. When the Chamber of Weights and Measures was established by the Department of Finance, in 1893, he was appointed conservator of the weights and measures. His proof of the periodic law (q.v.), first presented in 'Elements of Chemistry' (1868–70), is his crowning achievement in pure science. Consult Thorpe, 'Essays in Historical Chemistry' (1894).

MENDEL'S LAW, the law of heredity discovered by Johann Gregor Mendel (q.v.) and first published in 1865 under the title "Versuche über Pflanzenhydriden" in the *Proceedings* of the Society of Natural History of Brünn, Austria. Mendel made prolonged experiments in crossing varieties of the pea (*Pisum sativum*). His paper was overlooked until attention to his remarkable results was called by De Vries in 1900; he and also Correns and Tschermak at the same time independently rediscovered Mendel's law. Mendel selected seven pairs of characters, such as the shape of the ripe seed, of the cotyledons, of the seed-pod, color of the seed-skin, length of stem, etc. Large numbers of crosses were made between peas differing in respect of one of each of these pairs of characters. It was found, says Bateson, that in each case the offspring of the cross exhibited the character of one of the parents in almost undiminished intensity, and intermediates which could not be at once referred to one or other of the parental forms were not found. "In the case of each pair of characters there is thus one which in the first cross prevails to the exclusion of the other." This prevailing character Mendel called the dominant character, and to the other he gave the name of recessive character.

This law of dominance has been found by Bateson and by Castle to apply to animals as well as plants, and thus is a most important biological law. Thus when mating occurs between two organisms, whether vegetable or animal, differing in some character, the offspring frequently all exhibit the character of one parent only, in which case that character is said to be "dominant." For example, on crossing white mice with gray mice, Castle found that the offspring are gray, that color-character being dominant. The character which is not seen in the immediate offspring is called recessive, for though unseen it is still present in the young, white in the experiment being the recessive color.

The law of dominance has its exceptions; the hybrid often possesses a character of its own, instead of the pure character of one parent, as is true in cases of complete dominance. The hybrid form often resembles a supposed ancestral condition, when it is usually regarded as a reversion. Examples are the gray hybrid mice, which are indistinguishable in appearance from the house mouse; also slate-colored pigeons resulting from crossing white with buff pigeons.

One result of Mendel's discovery is the purity of the germ-cells. As stated by Castle: "The hybrid, whatever its own character, produces ripe germ-cells which bear only the pure character of one parent or the other." To breeders Mendel's law is of great importance because, as remarked by Castle, it reduces to an exact science the art of breeding in the case most carefully studied by him, that of entire dominance. "No animal or plant is 'pure' simply because it is descended from a long line of ancestors possessing a desired combination of characters, but any animal is pure if it produces gametes (germ-cells) of only one sort, even though its grandparents may among themselves have possessed opposite characters."

The bearings of Mendel's discovery, confirmed by De Vries' experiments, on the origin of species are most important. The problem is whether aberrations, sports or discontinuous variations may not sometimes result in the formation of new species and types, or whether species are all the result of slow, continuous variations. As stated by Castle, "A sport having once arisen affecting some one character of a species, may by crossing with the parent form be the cause of no end of disintegration on the part of any or all of the characters of the species, and the disintegrated characters may, indeed must, form a great variety of new combinations of characters, some of which will prove stable and self-perpetuating.

Mendel's discoveries also explain the principle that new types of organisms are extremely

variable, whereas old types are subject to little variation. A new type which has arisen as a sport will cross with the parent form. The offspring, says Castle, will then inherit some dominant character, others latent, and this will result in polymorphism of the race. Thus the suggestion of Galton that species may arise from sports is confirmed, while added cases are afforded by the recent remarkable experiments of De Vries, resulting in the origination of seven new species of primrose by sudden variations, or what he calls «mutations.» Consult Bateson, W., 'Mendel's Principles of Heredity' (Cambridge 1913); Castle, W. E., 'Mendel's Law of Heredity' (Cambridge 1903); Morgan, T. H., 'The Mechanism of Mendelian Heredity' (New York 1915). See HEREDITY.

MENDELSSOHN, Moses, měn'dĕls-sōn, German Jewish philosopher: b. Dessau, Germany, 6 Sept. 1729; d. Berlin, 4 Jan. 1786. His father, Mendel, a schoolmaster, though very poor, gave him a careful education. He lived several years on the charity of persons of his own religion, devoting his time to study, chiefly in Hebrew and Hebrew literature, but also in mathematics and modern languages. In 1750 he was appointed by a silk manufacturer named Bernhard, a Jew, tutor of his children. At a later period Bernhard took him as a partner in his business. In 1754 he became acquainted with Lessing, with whom he contracted a close intimacy, which had a great influence on his mind. Intellectual philosophy now became his chief study. His 'Briefe über die Empfindungen' were the first-fruit of his labors in this branch. Mendelssohn contributed to several of the first periodicals, and now and then appeared before the public with philosophical works, which brought him fame, not only in Germany, but also in foreign countries. The most celebrated of these is 'Phædon,' a treatise on the immortality of the soul, first published in 1767. It has been translated into most European languages. He established no new system, but was, nevertheless, one of the most profound and patient thinkers of his age, and the excellence of his character was enhanced by his modesty, uprightness and amiable disposition. He knew how to elude with delicacy the zealous efforts of Lavater to induce him to declare himself a Christian. To this encounter between Lavater and Mendelssohn German literature owes one of its greatest dramas, Lessing's 'Nathan der Weise,' in which the author, in the person of the hero, commemorates the virtues, the tolerant spirit and comprehensive mind of his friend Mendelssohn. His 'Jerusalem, oder über religiöse Macht und Judenthum' (1783) was much misunderstood, partly because he attacked many deep-rooted prejudices of his race. 'Morning Hours' (Morgenstunden) was published in 1785. The last work of Mendelssohn was in defense of his friend Lessing, of whom Jacobi had asserted that he was a Spinozist, was entitled 'Moses Mendelssohn und die Freunde Lessings' (1786). Consult Kayserling, 'Moses Mendelssohn' (1882).

MENDELSSOHN-BARTHOLDY, Jakob Ludwig Felix, German composer: b. Hamburg, 5 Feb. 1809; d. Leipzig, 4 Nov. 1847. The kindly influences which, like a halo, encircled the life of the illustrious man, are reflected in many of his best compositions. He was born in prosperity, reared in plenty and at nearly all times was surrounded by conditions conducive to success. It has been said that in no way was Mendelssohn's naturalness and naiveté more evident than in his constant reference to his own foibles; and further, that the hearty way in which he enjoyed idleness and boasted of it were delightful in a man who got through so much work, who was singularly temperate and whose only weakness for the products of the kitchen was for rice, milk and cherry pie. «I do not in the least concern myself,» said he, «as to what people wish or praise or pay for; but solely as to what I myself consider good.»

It is doubtful whether the history of any other great musician discloses so wide a combination of qualities. Some of his biographers have expressed the thought that his happy disposition prevented his work from attaining that degree of depth which it might have done had his genius been subjected to fiery trials. Be this as it may, the fact remains that among all the German composers there is not one who has enjoyed such universal popularity, certainly in America and England, as Mendelssohn. His oratorios, 'Saint Paul' and 'Elijah,' are sung everywhere, while his 'Hymn of Praise,' the 'Overture to the Hebrides,' his symphonies, sonatas, concert-overtures, settings for certain Psalms and 'Songs without Words' are familiar to all.

Seventy-two of Mendelssohn's numbered works were published before his death and 47 later, while 23 of his compositions, many of them including two or more pieces, had no «opus» numbers assigned to them. Six other of his published compositions have been recorded, while his unpublished pieces, mostly in autograph and principally composed before he was of age, are quite numerous, including 12 symphonies, several fugues, concertos, sonatas, studies, fantasias, etc.

Felix was the second child and eldest son of Abraham Mendelssohn, a Jewish banker of Hamburg, and Lea (or Leah) Salomon, a resident of Berlin, and a Jewish lady of considerable property and attainments, to whom he was married on 26 Dec. 1804. The grandfather of Felix was Moses Mendelssohn (q.v.), who settled in Berlin in 1762 and married Fromet, daughter of Abraham Gugenheim, of Hamburg. Moses' father was named Mendel, a poor Jewish schoolmaster of Dessau, on the Elbe. Thus the name Mendelssohn (son of Mendel) simply perpetuates the Oriental method of name-making.

When not three years old Felix was taken to Berlin, and five years later (1816) his father took him and his sister Fanny, four years the senior of Felix, to Paris on a business trip. While there they both received lessons on the piano from Madame Bigot, but it was not till after their return to Berlin that their systematic education commenced. Ludwig Berger became their piano instructor and Zelter taught them thorough-bass and composition. In 1824 Moscheles became acquainted with the family, and while he declined to accept Felix as a pupil consented to offer him suggestions and advice. In the same year Spohr visited Berlin and renewed his friendship with the family, which had been formed at Cassel in the summer of 1822 where the family had gone for

the purpose of introducing Felix to him. In his eighth year Felix played the piano with remarkable ability, and about a year later (1818) he made his first formal public appearance. This was at a concert given by Joseph Gugel, a virtuoso on the horn. At 11 he joined the Singakademie as an alto. In 1820 Felix commenced systematic work as a composer, although before that time he had written from 50 to 60 complete movements. The earliest date of which a dated autograph is preserved was attached to a cantata entitled 'In rührend feierlichen Tönen,' which he completed on 13 January of that year.

The following year was eventful. He composed five symphonies, nine fugues, several pieces for the piano, two operettas and a number of songs. It was in this year, too, that he visited Goethe at Weimar. The poet was delighted with his talent. While at Weimar he played before the Grand Duke and Duchess and improvised before the court and also before Hummel. His compositions in 1822 were very numerous, and during this and the following year he wrote six symphonies, five concertos, a piano quartet, a violin sonata, a Magnificat and Gloria, and an opera in three acts, entitled 'Die beiden Neffen, oder der Onkel aus Boston.' On 31 March he played for the second time in public, at Aloys Schmitt's concert, taking part in a duo for two pianos, and again, on 5 December, he played at a concert given by Madame Milder-Hauptmann, when he gave one of his own concertos. It was probably in this year, too, that the practice of having informal musical performances on alternate Sunday mornings at the Mendelssohn home was begun. Felix directed, his sister Fanny presided at the piano, his younger brother, Paul, played on the cello, and his second sister, Rebecca, sang.

In 1824 his musical genius showed marked advance, as evidenced in his symphony in C minor, composed between 3 and 31 March. In the summer he was taken to Doberan on the Baltic, a seaside resort, and there received the impressions which later found expression in his 'Meeresstille Ouverture.' His wonderful power of extemporizing and his readiness to play the music of other composers are noteworthy features, and Hiller, who was with him in Frankfort in 1825, was carried away with his performances. In this year he met Cherubini in Paris, whither he accompanied his father on a visit. Toward the end of 1825 Mendelssohn's father purchased a large mansion, surrounded by spacious grounds, and under the influence of this charming home he became more and more devoted to his work. The beauties of Shakespeare were here unfolded to him. Felix was especially charmed with the 'Midsummer Night's Dream,' and probably then conceived the idea of the exquisite composition bearing that name which forms opus 61 and was first produced in Potsdam 14 Oct. 1843. The overture to a 'Midsummer Night's Dream' appeared earlier, and as a piano duet, its first public performance being given at Stettin in February 1827. Either during this or the previous year, Felix entered the University of Berlin, where he showed evidences of decided literary powers. On his return from Stettin he made preparations for his opera 'Die Hochzeit des Camacho,' but owing to the opposition of the director, Spontini, it was performed only once at that time, although, strange to relate, a complete performance of it was given at Boston, Mass., on 19 March 1855.

The principal compositions during 1828 were a cantata for the Tercentenary Festival of Albrecht Dürer, a cantata for a Congress of Science, an antiphona for four voices, and a concert overture. He also completed his overture to Goethe's 'Calm Sea and Prosperous Voyage.' During this year he organized a choir of 16 voices for practising Bach's Passion music. The year 1829 was an important one for Felix. Hitherto his father had not permitted him to regard himself as a professional musician, but this now being determined on, arrangements were made for him to visit some of the great capitals, with a view of gaining materials for his greatest works. His first journey was to England, where he arrived on 21 April 1829. He was received with much enthusiasm and also scored a success in society. His delightful manners and unfailing animation charmed every one. In November he was again in Berlin, and during the winter he completed the 'Reformation Symphony' for the Tercentenary Festival of the Augsburg Confession. He declined the professorship of music in the university, preferring to carry out the program which his father had mapped out for him. In May 1830 he visited Weimar, where he again met Goethe, afterward going to Munich, and later to Italy. Preparations for his return began in June 1831, and after visiting many cities he arrived in Munich where his concerto in G minor was performed for the first time on 17 October.

Another visit to London was made in the spring of 1832, during which he composed with unabated vigor. Among the more important productions of this time were his musical representation of Goethe's 'Walpurgis Night,' and the 'Fingal Overture,' which was finished in Rome. Again in Berlin in July 1832, he gave several concerts, producing the 'Walpurgis Night' at one of them. His time was fully occupied in composing, playing and conducting. His 'Italian' symphony was completed in March 1833, and sent to London where it was produced on 13 May under his personal direction. Later in the month, we find him conducting the Lower Rhine festival in Düsseldorf, where, as a result of his success, he was engaged as director of "all the public and private establishments of the town" for three years with a salary of 600 thalers. He resigned, however, during the second year to accept the position of conductor of the famous Gewandhaus Concerts at Leipzig, then considered the highest position in the musical world of Germany. Thither he proceeded in August 1835, to make arrangements for the season which began on the 4th of October following. Seven concerts were given between that date and 20 November, when he was shocked by the news of his father's death which had occurred the day before. For the first time his radiant disposition forsook him and he fell into a despondent mood. During this season of sadness, however, he was able to finish the oratorio of 'Saint Paul' while he also maintained the excellence of the concerts for which he was responsible. The great oratorio was first produced at the Lower Rhine Festival at Düsseldorf 22 May

1836. About this time he took charge of the Frankfort Cäcilien-Verein during the illness of the director, and there made the friendship of Madame Jean-Renaud and her family. He became devotedly attached to her youngest daughter, Cécile, to whom he was married on 28 March 1837. Returning to Leipzig he conducted another successful season, closing with a performance of 'Saint Paul,' for the first time produced in that city. In August 1837, he left his bride for the purpose of conducting 'Saint Paul' at the Birmingham Festival. This was his fifth journey to England, and before he returned he held conferences with his friend, Klingermann, over the plan of a new oratorio having the prophet Elijah as the central figure. He reached Leipzig on 1 October in time to conduct the first concert of the Gewandhaus on the same evening.

The year 1839 was notable for the composition of the 'Ruy Blas' overture for the Leipzig Theatre and the setting of the 114th Psalm to music. In the following year the invention of printing was celebrated in Leipzig by a festival, and the 'Festgesang,' for men's voices, and 'Lobgesang,' or 'Hymn of Praise,' were composed for the occasion. During this year Mendelssohn accepted the direction of the musical department of the Berlin National Academy of Arts, but before entering his duties he made another visit to Birmingham to conduct a performance of the 'Hymn of Praise.' On his return he was installed as General-Musik-Director in Berlin, but having the privilege of living where he pleased, he returned to Leipzig. About this time he composed the music for the 'Antigone' and 'Œdipus Coloneus' of Sophocles, Racine's 'Athalie' and Shakespeare's 'Tempest' and 'Midsummer Night's Dream.'

Another sad trial now befell him in the death of his mother, 12 Dec. 1842, and in November of the following year he removed to Berlin. The king of Saxony had recently established a conservatory of music, a plan which Mendelssohn had long cherished, and he and Schumann were appointed professors of composition and the piano. Meanwhile the Gewandhaus concerts were left in charge of Hiller. In 1844 he visited London for the eighth time in response to an invitation to direct several concerts of the London Philharmonic Society. In October he resigned his position as General-Musik-Director in Berlin and took a much-needed rest until the autumn of 1845 when he again assumed charge of the Gewandhaus orchestra.

Early in 1846 he was back in Leipzig where he took charge of two classes in piano and composition, and among his pupils were Goldschmidt, De Sentis, Tausch and others. The season of 1845–46 was unusually brilliant in concert work and the program showed a great breadth of selection. At the eighth concert he brought with him Jenny Lind, who was then heard for the first time in Leipzig. On 5 Aug. 1846, a preliminary rehearsal of 'Elijah' was held in Leipzig and soon after he started for England on his ninth visit, the complete score having been sent over a month earlier for translation. First there was a rehearsal with piano accompaniment at Moscheles' house, followed by two full rehearsals at the Hanover Square Rooms, and later by rehearsals in Birmingham, where on 26 August the oratorio was performed for the first time in public. One of his biographers states that "there was a mad rush at the close of the performance to grasp the hand of the hero of the day, who thanked all present for their share in the performance with which he was so deeply gratified." Returning to Leipzig he remodeled the oratorio, however, making so many changes that scarcely a movement stands to-day as it was originally written. The complete edition was published in July 1847. The Sacred Harmonic Society of London now invited Mendelssohn to give a production of 'Elijah' in its revised form in Exeter Hall, and for the tenth and last time he visited London in April 1847. Four performances were given, Queen Victoria and the Prince Consort being present at the second of the series. After giving other productions of the 'Elijah' in Manchester and Birmingham, followed by a performance with the Philharmonic Society, he returned to Frankfort, weary and utterly worn out. To add to his now unhappy condition, his sister Fanny, whom he had loved devotedly, was stricken with paralysis and died 14 May 1847. On hearing the sad news he fell fainting and for several weeks was utterly prostrated. Seeking diversion, he revisited Switzerland during the summer, where, it is said, he applied himself to water-color painting and made excellent progress in that direction. Later he resumed composition, numbering among his productions at that time the beautiful quartet in F minor (Opus 80), and he also wrote some parts of a newly commenced oratorio, 'Christus,' which he left unfinished. He returned to Leipzig in September, but attempted nothing serious in a musical way. His spirit was broken and he dreaded to appear in public. The beginning of the end came on 9 October while calling on Madame Frege, whom he was accompanying in his last set of songs. She left the room to order lights, says one of his biographers, and on her return found him shivering and suffering violent pains in the head. He rallied somewhat, but another relapse occurred on 3 November and he never spoke again. He died the following day and on Sunday, the 7th, was borne to the Paulinen-Kirche, preceded by a band playing one of his 'Lieder ohne Worte' (Book V, No. 3), which Moscheles had scored for the occasion. Thence the coffin was taken to the Alte Dreifaltigkeits-Kirchhof in Berlin, where it was deposited in its last resting place.

A cross on the grave bears this inscription: "Jakob Ludwig Felix Mendelssohn-Bartholdy: geboren zu Hamburg, am 3 Feb. 1809; gestorben zu Leipzig am 4 Nov. 1847."

RANDOLPH I. GEARE,
Official United States National Museum until 1917. Bibliography brought to date by Americana Editorial Staff.

MENDENHALL, mĕn'dĕn-hôl, **Thomas Corwin,** American physicist; b. near Hanovertown, Ohio, Oct. 4, 1841; d. Ravenna, Ohio, March 23, 1924. He was educated in the public schools and by his own efforts obtained a knowledge of physics and higher mathematics. In 1873 he became professor of physics and mechanics in the Ohio University, where he remained until 1878, when he accepted a call to the chair of physics at the Imperial University in Tokio, Japan. There he founded a laboratory, an observatory, a scientific society, inaugurated a system of lectures, which work was highly approved by the Japanese government. In 1881 he returned to the Ohio University, and in 1884 accepted a position in the Signal Service at Washington. In 1886 he was elected president of the Rose Polytechnic Institute, but resigned in 1889 to become superintendent of the United States Coast and Geodetic Survey, and from 1894–1901 was president of the Worcester Polytechnic Institute. He published several scientific papers and a book entitled *A Century of Electricity* (1887).

MENDENHALL, Walter Curran, American geologist: b. Marlboro, Stark County, Ohio, Feb. 20, 1871. In 1895 he was graduated at Ohio Normal University; studied at Harvard in 1896–1897 and at Heidelberg, Germany, in 1899–1900. In 1894–1896 he was geologic aid, in 1896–1901 assistant geologist and from 1901 until his retirement in 1944, he was chief geologist of the United States Geological Survey. He had charge of the ground-water investigations of the survey in 1907–1910, from 1910 until 1922 served as chief of the Land Classification Board when he became chief geologist. He is the author of various memoirs and articles on professional topics.

MENDERES, mĕn-dĕ-rĕs', the ancient Maeander (q.v.), a river of western Turkey in Asia. Rising in the mountains west of Afyon Karahisar, it flows southwest and west for more than 200 miles, emptying in the Aegean Sea south of the island of Samos. Another river in Asiatic Turkey, likewise called the Menderes, is the ancient Scamander (q.v.) which rises in Kazdagi (Mount Ida) and flowing west and northwest for about 60 miles, after crossing the plains of Troy, debouches in the Dardanelles at Kumkale near the Aegean entrance.

MENDES, măn-dĕs', **Catulle,** (in full ABRAHAM CATULLE MENDES), French writer: b. Bordeaux, May 22, 1841; d. Paris, Feb. 8, 1909. His verse is marked by extreme devotion to form. He also wrote a great deal of prose—short stories, longer works of fiction, dramas. There is much affectation about them all.

Among his books are *Poésies* (1878); *Monstres Parisiens* (1882); *La Rose et le Noir* (1885); *Grande Maguet* (1888). Of his plays may be cited *Le Capitaine Fracasse* (1872) and *Fiamette* (1889).

MENDES LEAL DA SILVA, măn'dāsh lā-äl' dä sĕl'vä, **José,** Portuguese statesman and poet: b. Lisbon, Oct. 18, 1818; d. Cintra, Aug. 14, 1886. He was minister of the navy and of foreign affairs; ambassador to France, 1874–1883; and to Spain, 1883–1886. His vogue as a poet has been very great in his own country and his *Songs* (*Canticos*) were first collected in 1858. He wrote also a large number of plays, some of them very popular on the Portuguese stage as *Uncle Andrew from Brazil;* and *The Sportsman;* and also several romances. He became a member of the Portuguese Academy in 1845.

MENDEZ-PINTO, măn'dāsh pēn'too, **Fernao,** or **Fernam,** Portuguese traveler: b. Montemor-o-Velho, near Coimbra, Portugal, about 1510; d. Almada, near Lisbon, Portugal, July 8, 1583. He departed for the Indies in 1537, returning in 1558, and after his death a very curious account of his voyages, *Perigrinação de Fernam Mendez-Pinto,* appeared (1614), which was translated into French, English and other European tongues. Congreve, in his *Love for Love,* called him "a liar of the first magnitude," and from that time his narrative was considered as a romance; but his good faith and veracity are now generally admitted.

MENDIBURU, măn-dē-bōō'rōō, **Manuel de,** Peruvian soldier and historian: b. Lima, 1805; d. there, Jan. 21, 1885. While a student he joined the patriot forces in 1821, was captured by the Spanish and held prisoner till the close of the war. Among various civil and military posts afterward held by him were those of minister of war and finance.

He published a *Diccionario historico-geografico del Peru,* a work of great value and highly prized by scholars. The first part, in eight volumes, deals with the Inca and colonial periods, and its publication, begun in 1874, was concluded after General Mendiburu's death. The second part was not published.

MENDICANCY, mĕn'dĭ-kăn-sĭ. The experience of all countries has shown that mendicancy will thrive wherever indiscriminate almsgiving prevails. As early as 1351 France was compelled to pass laws against begging. England forbade it in the time of Henry VIII, and Italy in 1865. The local authorities in the latter country, however, are allowed to issue permits, and medicants abound. Seville is the only city in Spain where begging is not allowed.

In the United States, where work is, on the whole, plentiful, there is little or no excuse for mendicancy, and it is forbidden by law. Paupers are cared for in public institutions, and casual unfortunates by private charitable institutions. Yet there are professional beggars in nearly all the larger cities of the United States. See also MENDICANT FRIARS.

MENDICANT FRIARS, are religious orders which depend entirely on the alms of the faithful for their support. While no individual monk or nun can hold or use property for personal profit, most communities as such possess property in the form of endowments or commercial enterprises for their common support.

In the 13th century a new spirit of enthusiasm sprang up under the teaching of St. Francis and St. Dominic, and orders of friars were founded, which were forbidden to possess property in any form beyond the houses in which they dwelt. The most notable of these were the Carmelites, Franciscans, and Dominicans. The Augustinians soon followed their example; and in 1487 the Servites were also officially recognized as a mendicant order. At first the members of these orders actually begged their bread from door to door; but this soon ceased.

MENDIETA Y MONTEFUR, měn-dyā'tä ē mōn-tä-fōōr', **Carlos,** Cuban physician and provisional president: b. San Antonio de las Vueltas, Nov. 4, 1873. Joining the forces of Antonio Maceo in the 1895 revolution he rose to the rank of colonel. After Cuban independence he studied medicine at the University of Havana which awarded him the M.D. degree in 1902. A candidate of the Partido Liberal for the vice presidency in 1916, he was subsequently a political prisoner, then exiled. In January 1934 he was installed as provisional president by Fulgencio Batista (q.v.), but being unable to establish a stable government he resigned in December 1935.

MENDIVE, mān-dē'vā, **Rafael Maria de,** Cuban poet: b. Havana, Cuba, Oct. 24, 1821; d. Matanzas, Cuba, 1886. His first collection of poems (1847), entitled *Passion-Flowers,* is widely popular. Banished in 1869, he lived alternately in New York and Nassau, writing legends and stories in verse. He was one of the most notable of Spanish-American poets; and many of his verses received English, French and Italian translations.

MENDOCINO, Cape, měn-dō-sē'nō, the westernmost point of the coast of California, projecting into the Pacific Ocean in latitude 40° 26′ north and longitude 124° 25′ west. It has a very high lighthouse, 422 feet above sea level, with a flashing light.

MENDOTA, city, Illinois, in La Salle County, 83 miles west of Chicago; on the Chicago, Milwaukee, St. Paul and Pacific, the Illinois Central, and the Chicago, Burlington and Quincy railroads. The city contains the Blackstone School, the Lincoln School, a high school, and a parochial school, as well as a public library. Its manufactures include coal, gas and oil stokers, time controls, and automatic gluing and veneer presses, and it has a large-sized corn packing plant. The municipality owns the water-supply system and the sewage system. Pop. (1940) 4,008; (1950) 5,129.

MENDOTA, village, Minnesota, in Dakota County, across the Mississippi River from St. Paul and just below the juncture of the Mississippi and Minnesota rivers; altitude, 703 feet. Mendota was the first permanent white settlement in the state. Here Alexis Bailly of the American Fur Company traded with the Indians from before 1819, his trading post being known as St. Peter's. The permanent settlement dates from 1834 when Henry H. Sibley (q.v.) succeeded Bailly. Three years later the name of the village was changed to Mendota. Sibley's house, built in 1835, is preserved. Pop. (1950) 228.

MENDOTA LAKE. See FOUR LAKES.

MENDOZA, mān-dō'sä, **Antonio de,** Spanish administrator: b. about 1485; d. Lima, Peru, July 21, 1552. In 1535 he was appointed by the Emperor Charles V, with whom he was in great personal favor, viceroy of New Spain (Mexico), being the first of 64 viceroys, with the longest administration and that which shows the best record in the history of that provincial government. He made many reforms, especially in relieving the oppressed natives; developed agriculture and mining; established the first Mexican mint; founded the first college; and introduced the first printing press.

In 1551 he became viceroy of Peru, where he caused to be prepared a code of laws that has been the basis of the colonial and, to a large extent, of the present legal system of the republic. It was under Mendoza's administration in Mexico that Francisco Vásquez de Coronado (q.v.) undertook his famous exploring expedition.

MENDOZA, mān-dō'thä, **Diego Hurtado de,** Spanish author and statesman, great-grandson of the Marqués de Santillana (q.v.): b. Granada, about 1503; d. Madrid, April 15, 1575. He was educated, as a younger son, for the church, but, after studying Arabic at Granada and the humanities at Salamanca, entered the army and in 1525 fought at Pavia. He acted as Charles V's ambassador to England in 1537, to Venice in 1539; was representative at the Council of Trent (1545), governor of Siena (1547), and imperial representative to the papal see in Rome (1549). With Philip II he quarreled and in 1564 was interned in Granada, only returning to court in 1574, soon before his death. To his stay in Italy was due his influence in making the Spanish lyric thoroughly Italianate; and from Italy he brought an unusual knowledge of the classics as well as a fine collection of Greek manuscripts. Mendoza also perfected the Spanish poetic epistle. The famous romance, *Lazarillo de Tormes* (q.v.), has been ascribed to him. But his greatest work is his history of the Moorish insurrection, *Guerra de Granada,* a model of historical impartiality and on a theme for which knowledge of Arabic peculiarly fitted him. So impartial was this work that it was not published complete for many years.

MENDOZA, Pedro de, Spanish soldier, explorer, and colonizer, founder of Buenos Aires: b. Guadix, Granada, Spain, about 1487; d. at sea, 1537. He was a favorite of Charles V; fought bravely in Italy; and in April 1535 left Spain with 12 ships and 800 men, sailed up the Plata River in South America and founded the city then called "Nuestra Señora de Buenos Ayres." His further movements were unfortunate; Indians and disease attacked his men, three fourths of whom, including his own brother, were lost. The natives captured and burned the city, and Mendoza, rescued none too soon by his brother, who came with reinforcements, set sail for

home. But his health and reason were undermined and he died on board ship.

MENDOZA, Argentina, a province in the western part, on the eastern slope of the Andes Mountains; area, 56,502 square miles. Mount Aconcagua, 22,427 feet, is on the northwestern boundary. The western part of the province is mountainous, the eastern part pampa land and fertile where watered by the streams or by irrigation, but the climate is hot and dry. There are four important rivers, the Mendoza, Atuel, Diamante and Tunuyan. The Transandean Railway from Valparaiso to Buenos Aires divides the territory. There is also a railway to San Juan and San Carlos, and a southern line from San Rafael east. It is rich in minerals, especially silver and copper. Coal and petroleum abound. Grapes grow luxuriantly and a large quantity of wine is shipped to the other provinces. Cattle, hides and wool are the chief exports. Wheat and corn are increasing in importance. Pop. 496,000.

MENDOZA, Argentina, city, capital of the province of Mendoza, at the base of the Andes, on the eastern side of the mountains, on the railroad which extends from Buenos Aires to Valparaiso, Chile, about 600 miles west by north from Buenos Aires and 165 miles east of Valparaiso. It is about 2,400 feet above the sea. The city was founded in 1559. It belonged to Chile previous to 1776. In 1861 it suffered from an earthquake which killed about 10,000 people and destroyed a great part of the city. The Transandean Railway connects the city via Villa Mercedes with all the large cities of the eastern coast, also with Santa Fe and Corrientes. It has churches, banks, department stores and is an important trade centre. It is the seat of two national normal schools, a national college and an agricultural institute. Pop. about 82,000.

MENE, mē'nē (numbered); **TEKEL** (weighed); **UPHARSIN** (divided), the Chaldee words traced on the wall at Belshazzar's feast and significant of his impending doom (Dan. v). The astrologers could not read them, because they were written in antique Hebrew characters, but Daniel understood their awful meaning; and the same night witnessed their fulfilment.

MENEDEMUS, founder of the school of philosophy called Eretrian from his native city Eretria: b. about 351; d. about 277 B.C. Traditions vary as to whether he turned to philosophy under the influence of Plato, or under that of Stilpo of Megara, but his tenets seem to have most resembled those of the Megarian school.

MENELAUS, měn-ē-lā'ŭs, *in Greek legendary history,* the son or grandson of Atreus and brother of Agamemnon (q.v.). From his father-in-law, Tyndareus, whose daughter Helen he married, he received the kingdom of Sparta or Lacedæmon. Paris, son of Priam, king of Troy, having carried off his wife, Helen, with a part of his treasures and some female slaves, and conveyed them to Troy (q.v.), Menelaus, accompanied by Ulysses (q.v.), went thither to demand the restitution of his wife and property, and this being refused, he summoned the Greek princes to revenge the affront according to their promise. After the conquest of Troy, Menelaus took Helen to return with her to his native land. Eight years he wandered before he reached home. On the island of Pharos (q.v.) he surprised Proteus asleep and compelled him to disclose the means which he must take to reach home. See TROJAN WAR.

MENELIK II, měn'ĕ-lĭk, emperor (Negus Negusti—King of Kings) of Abyssinia: b. 1844; d. December 1913. The son of a king of Shoa, he secured the throne in 1889, in which year he signed the Treaty of Uccialli with Italy. He discovered some years later that by the Italian text of the treaty he was bound to conduct his foreign affairs through the Italian government, while the Amharic text made this optional. He accordingly wrote to Queen Victoria in 1893 and protested against the treaty as infringing upon his sovereign rights. In 1896 he fought a war with the Italians and severely defeated them in the battle of Adua. His complete independence was then recognized by Italy and the other European powers. He concluded treaties of commerce with Great Britain and other countries and co-operated with the British army against the Sudan dervishes. A humane and just ruler, he endeavored to apply the arts of civilization to his backward country. He was succeeded by his nephew Lij Yasu, deposed in 1916.

MENENDEZ DE AVILES Y MARQUEZ, mā-nĕn'dĕth dā ä-vē-lās' ē mär'kĕth, **Pedro,** Spanish captain, founder of the city of Saint Augustine, Fla.: b. Aviles, Austria, 1519; d. Santander, 17 Sept. 1574. In June 1565 he sailed with 1,500 men in 19 vessels to dislodge the French in Florida; landed there 28 August; and 6 September began a fort, the nucleus of the present town. He attacked the French garrison at Fort Caroline, during the absence of part of the force, which had set out to attack him but was storm-stayed and finally wrecked. Menendez slaughtered the remnant at the fort and those saved from shipwreck. He returned to Spain in 1567; visited America twice again, strengthening Saint Augustine in 1568, and in 1570 sending a party of colonists to the Chesapeake and up the Rappahannock, where they were massacred by the natives; and was recalled to Spain shortly before his death. During the last two years of his life he was governor of Cuba. Consult Winsor, J., 'Narrative and Critical History of America' (New York 1886).

MENENDEZ Y PELAYO, ē pā-lā'yō, **Marcelino,** Spanish critic: b. Santander, 3 Nov. 1856; d. there, 19 May 1912. He was educated at Madrid and Paris; in 1878 became professor of philosophy and letters in Madrid; three years later was elected to the Spanish Academy; and in the late nineties became director of the Biblioteca Nacional. He lectured often, especially at the Athenæum in Madrid. For several years he was dean of the faculty of letters at the University of Madrid, he served a term as senator, was counsellor of public instruction and chief of the board of archivists. He received many honors, including the grand cross of the Order of Alfonso XII. His literary style was finished and elegant and he was ever a staunch defender of Catholicism. He wrote 'Estudios criticos sobre Escritores Montañeses' (1876); 'Horacio en España'

(1877); 'Historia de los Heterodoxos Españoles' (1880–81); 'Calderon y su Teatro' (1881); 'Odas, Epistolas y Tragedias' (1883); 'Historia de las Ideas estéticas en España' (1884–91).

MENENDEZ PIDAL, Ramon, Spanish critic, philologist, educationalist and general literary man: b. Coruña, 13 March 1869. Educated at the universities of Madrid and Toulouse he became professor of Romanic philology at the former (1899). See PIDAL, RAMON MENENDEZ.

MENEPTAH, or **MERNEPTAH,** king of Egypt about 1250 B.C. He succeeded his father, Rameses II, and reigned for a period of 20 years. His reign was troubled by an invasion from Libya, but he succeeded in crushing it and thereafter set about the construction of numerous buildings and monuments, especially at Tanis. In 1898 his mummy was discovered at Thebes and now reposes in the Cairo Museum. Previous to 1896 it was thought that Meneptah was identical with the Pharaoh of the Exodus, but in that year an inscription was uncovered in which it was stated that Israel was settled in Palestine in the fifth year of Meneptah. This inscription is of prime historic interest as fixing the period of the settlement of Israel in Palestine and as the only mention of Israel on Egyptian monuments. For the inscription consult 'Der Sieges-hymnus des Meneptah auf der Flinders Petrie Stele' (in *Zeitschrift für ägyptische Sprache,* Vol. XXXIV, Leipzig 1896). Consult also Breasted, J. H., 'History of Egypt' (2d ed., New York 1909) and Budge, E. A. T. W., 'History of Egypt' (New York 1902).

MENES, mē'nēz, according to Egyptian traditions, the first king of Egypt. Herodotus relates that he was the founder of Memphis, which he built on a piece of ground which he had recovered from the Nile by altering the river's course. According to Diodorus, Menes introduced into Egypt the worship of the gods, as well as a more elegant style of living. He has been identified by some with the Mizraim mentioned in Gen. x, 6. A tomb supposed to be that of Menes was discovered near Nakâdeh by De Morgan in 1897. Consult Breasted, J. H., 'History of the Ancient Egyptians' (New York 1908). See EGYPT.

MENG CHIANG. See MONGOLIA.

MENG-TSE, měng-tsĕ'. See MENCIUS.

MENGER, Karl, Austrian political economist: b. Neu-Sandez, Galicia, 1840; d. 27 Feb. 1921. He studied at the universities of Vienna and Prague, giving special attention to law and political economy. In 1872 he began his long connection with the University of Vienna, being appointed full professor of political economy in 1879. He was created life member of the Austrian House of Peers in 1900. As an economist he was undisputed leader of the new school of economics in his country and was opposed to the traditional system hitherto followed. He published several important works, including 'Grundsätze der Volkswirtschaftslehre' (1871); 'Untersuchungen über die Methode der Sozialwissenschaften und der politischen Oekonomie insbesondere' (1883); 'Die Irrtümer des Historismus in der deutschen Nationalökonomie' (1884); 'Beiträge zur Währungsfrage in Oesterreich-Ungarn' (1892) and the article "Geld" (in 'Handwörterbuch der Staatswissenschaften,' 3d ed., 1909).

MENGS, Anton Raphael, German painter: b. Aussig, Bohemia, 12 March 1728; d. Rome, 29 June 1779. In early childhood his father, Ismail Mengs, a miniature painter of little talent, who was settled at Dresden, took him in hand to make a painter of him, and in 1741 carried him to Rome and set him to study the antique and to copy Michaelangelo and Raphael. He was compelled to do a certain task in painting every day; his day's work subjected to severe criticism; and he was even punished if it was not satisfactory. From this constant practice he early gained skill as an artist, and when he returned to Dresden his talent and proficiency were at once recognized by August III, who appointed him court painter and gave him permission to return to Rome. At Rome he attended the Academy and in 1748 produced a large and elaborate composition, 'The Holy Family,' taking as model for the Mother of Jesus a beautiful peasant girl, whom he afterward married. On his return to Dresden he was commissioned to paint an altar-piece, 'The Ascension of Christ,' for the high altar of the Chapel Royal, and was given permission to return to Rome for the purpose of doing so. A new academy of painting having been opened in the capitol he was appointed director and painted for the Celestines the ceiling of their church, San Eusebio, for Cardinal Albani the 'Parnassus' in the ceiling of his villa, and several oil paintings, including 'Cleopatra,' 'The Holy Family' and 'The Magdalen' for private persons. When King Charles III of Spain summoned him to Madrid he executed for him in fresco there 'The Assembly of the Gods' and 'The Descent from the Cross'; he also completed the altar-piece for Dresden. He returned to Italy in 1769, stayed eight months at Florence and painted for the Pope a ceiling fresco for the Vatican Library. In 1772 he went to Spain and produced for the king the fresco 'Apotheosis of Trajan,' his finest work, but returned to Rome in 1775. On his death the Cavalier d'Azara set up a statue to him and Catherine II of Russia raised a splendid tomb for him in Saint Peter's. He was certainly one of the most important painters of his day, and if he possessed none of the free and living originality of genius he was a master of noble composition and design. He was catholic in taste and eclectic in style, drawing inspiration from the antique, as well as imitating Raphael, Titian and Correggio, whose styles he tried to blend. Consult Woermann, 'Ismail und Raphael Mengs' (in the *Zeitschrift für bildende Kunst,* No. 5, 1893).

MENHADEN, a species of fish (*Brevoortia tyrannus*) of the herring family (*Clupeidæ*), appearing in vast schools along the Atlantic Coast of America. Owing to the large number of local names applied to this species much confusion concerning its identity and distribution exists in the minds of fishermen and others. The name "menhaden" (Indian) is used chiefly in southern New England. North of Cape Cod the fish is called pogy, or occasionally hardhead; in New York and New Jersey, bunker or marshbunker; the fishermen of Delaware

and Chesapeake bays know it as bay alewife, and in the latter region and southward also as bug-fish or bug-head; still farther south it becomes the fat-back, and so on. From the other herrings the menhaden is readily distinguished by its very large head, large mouth, complex gill strainers and crenulated scales. The body is deep, the fins small, the mouth toothless and the color bluish and silvery, with one large and several small black spots.

Like some other pelagic and migratory fishes the menhaden is exceedingly irregular in its movements and variable in abundance and distribution from year to year, but its general range is from Nova Scotia to Brazil and oceanward, so far as observed, to the Gulf Stream. In spring it approaches the coasts and extends northward with the alewives and other species, probably for the purpose of spawning in brackish water, though little is actually known of its spawning habits. In winter Cape Hatteras marks the northern limit of its abundance. The menhaden swims in compact schools of large size, the movements of which at the surface, or sunken to a greater depth, are extremely irregular.

These irregularities are owing, no doubt, to corresponding variation in its food-supply, which consists wholly of the minute organisms, both vegetable and animal (plankton), that are caught as the fish swims with open mouth, straining the water through its lips and gill-arches as it goes. Owing to its strong oily taste and extreme bonyness its value as human food is very slight, but as furnishing food for other fishes, as bait, and for the manufacture of oil, fertilizer and other products, it has a very great economic importance. Large companies control its capture for the latter purposes and, besides pound nets, utilize many steamers provided with purse seines and derricks, by means of which entire schools are taken at a haul and lifted on deck. The oil is extracted and the solid parts ground up for fertilizer at factories on shores. The product varies from year to year, but the total weight of fish taken runs into the hundreds of million pounds. The catch of fish and industries involved reached their highest level of importance in the latter part of the last century, since which both have much diminished, whether by reason of over-fishing or because the menhaden no longer come to the northern part of the coast in so great abundance, is not determined. Consult Goode, 'History of the Menhaden,' Report United States Fish Commission, 1879, and recent reports of the United States Bureau of Fisheries.

MENHIRS, elongated, rough-hewn monoliths standing with one end in the ground. They are found of various sizes, from about 6 to as much as 67 feet high, the latter being the height of that at Locmariaquer in Brittany. Singular superstitions naturally attach to some of them. See STONES, STANDING.

MENIERE'S DISEASE, a disease of the ear first described by the French physician, Emile Antoine Ménière, in 1861. It is one form of auditory vertigo and usually attacks persons of middle age. The principal causes are sunstroke, influenza, rheumatism, anæmia and venereal diseases. The attack is usually very sudden and appears to be due to hæmorrhage into the labyrinth. The seizures may occur at irregular intervals of days or even weeks. While the symptoms of dizziness, vertigo, nausea, etc., gradually disappear the deafness is generally permanent. Potassium iodide is most serviceable in reducing the dizziness. See EAR.

MENIN, Belgium, town in the province of West Flanders, on the Lys and on the Belgo-French frontier here demarcated by the river, seven miles southwest of Courtrai, and 30 miles southwest of Ghent. It contains lace and cotton mills, tobacco factories, etc. In the neighborhood there were extensive tobacco plantations previous to the war of 1914–18, in which Menin suffered severely. It fell to the Germans during the great rush of both armies northward to the sea; was taken by the British in a spirited attack, but was subsequently evacuated by them for strategic reasons. The British having noted a German concentration of troops and *materiel* in Menin made an aerial attack upon it which brought damage to a great number of buildings. Pop. 18,600.

MENINGITIS. The brain is enveloped by three membranes called the meninges. Next to the skull comes the dura mater, then the arachnoid and innermost is the pia mater. These three membranes are prolonged from the brain in three envelopes of the spinal cord. Meningitis is an inflammation of the meninges of the brain or of the spinal cord. It is very rarely a primary condition, but is usually secondary to infection from micro-organisms of many types, or results from chronic poisonings such as lead, alcohol, etc. Hence modern medicine speaks of various meningitides rather than one meningitis. When the surface of the brain is wounded by some object breaking through the skull, or a piece of broken bone of the skull, thrust inward by some blow, an artery is ruptured and the blood flows between the membranes. Such a condition is called *traumatic meningeal hæmorrhage.* When the dura mater becomes inflamed after a wound, or after inflammation of other parts of the head, as the ears, teeth, etc., there, results a condition called *pachymeningitis externa.* Inflammation of the meninges, however, is generally confined to the pia mater and the arachnoid and is then called *leptomeningitis,* Pachymeningitis, inflammation alone or chiefly of the dura mater, may extend to the other membranes. Inflammation of the cerebral meninges is *cerebral meningitis;* of the spinal meninges, *spinal meningitis;* of those of the brain and spinal cord together, *cerebro-spinal meningitis.* Ascending meningitis is a meningitis ascending from the lower part of the spinal cord.

Pachymeningitis has one form involving the external surface of the dura mater and resulting from blows or other injuries, and from osseous growths. There may be no well-defined symptoms, but usually is local headache and tenderness on pressure. The onset is usually sudden. Many cases of meningitis of the type called «serous» are not other than pachymeningitis. If the dura mater, which is normally free, is bound to the skull by fibrous exudation, and especially if pus forms and hæmorrhages occur, there are symptoms of pressure. Inflammation of the internal portion

of the dura mater may result from the extension of inflammation from adjacent parts, such as the ear, the frontal or the ethmoidal sinus; or it may attend cases of pernicious anæmia, chronic syphilis, tuberculosis and chronic infectious diseases. It occurs chiefly in old age, but has been seen in children. There are fibrinous deposits and extravasation of blood in cysts (hæmatoma), and occasionally pus forms. The brain is anæmic, sometimes softened. The symptoms are those of irritation — convulsions, vomiting, dilated pupils which are not affected by exposure to light, a slow irregular pulse, etc.—and those of compression or pressure—coma, etc. Pachymeningitis is usually fatal.

Cerebral meningitis (simple or cerebral meningitis), in the acute form, is not common, and is most apt to occur in men engaged in hard mental pursuits. It may be caused by injuries, by sunstroke, by spirituous liquors, etc., and is very dangerous, death usually occurring in from three to eight days. The brain is reddened and covered more or less with pus and coagulated fibrin or lymph, and its superficial layer is softened. There is almost always serous effusion into the brain-cavities. The symptoms are those of three stages: (1) Headache; (2) delirium; (3) coma. At first there may be slight fever, some photophobia, frequency and irregularity of the pulse and some contraction of the pupils. There is a disposition to vomit, a slowness in movements of the bowels and often hyperæsthesia. Then comes delirium, which may or may not be active; the patient talks much and tries to get out of bed; does not obey readily. There is more or less trembling of the limbs, with difficulty in moving them. One pupil is likely to be dilated. Sometimes strabismus occurs; the pulse is very irregular; and paralysis begins. Then follows coma, loss of sense, sensation and of voluntary motion; there is sighing, the pulse is frequent and weak, the pupils do not respond readily to light and the capillaries of the skin and eye are congested. Recovery from this disease rarely occurs after the period of coma begins.

Sub-acute or chronic cerebral meningitis is a secondary disease, sometimes associated with chronic syphilis, Bright's disease, alcoholism, etc., though the cause is not always ascertained. The lesions are similar to those of acute meningitis, but less pronounced. There is less of serum and pus, and the exudated fibrin is more circumscribed. The symptoms are insidious and vague. Headache, vomiting and photophobia are rare. The slight delirium is followed, it may be, by somnolency, irregular pulse, strabismus and sighing respiration. With coma the pulse is rapid, 120 or more, and the patient dies as in acute meningitis.

Tuberculous meningitis, also known as acute hydrocephalous, granular meningitis and basilar meningitis, is an acute tuberculous inflammation of the pia mater, caused by a deposit of miliary granules over the surface of the brain, but most numerous at the base, in the track of the cerebral vessels, and in their sheaths. There is a noticeable vascularity, especially in the ventricles. The pia mater is thickened and opaque and covered with a semi-purulent exudation. Serum fills the ventricles and formina, pressing upon the convolutions, and assists in softening portions of the brain. The lesions in this disease are rarely limited to the brain; tubercles are found in other organs, especially the lungs. The disease is a phase of that protean malady, tuberculosis, though the cerebral lesions may first be noticed. The primary causes are a hereditary diathesis (scrofulous or tuberculous), foci of caseous degeneration in some organ, a suppurating joint, or a scrofulous inflammation of bone. The physically weak children of tuberculous parents are most subject to this disease, and in cases where strong children are attacked there is generally found a tubercular relative. Though the disease is essentially a disease of early life (from nine months to 10 years), it also attacks adults. Most of those affected die in from two to six weeks. The symptoms may be classed under three heads: (1) Obscure symptoms; (2) those of rapid development; (3) those of coma. There are seen listlessness, loss of appetite, occasional vomiting, slowness of the bowels and somewhat frequent pulse. Sometimes there is headache, a remittent form of fever and then rapid development of diagnostic symptoms. The patient talks a good deal. One of the most important symptoms is a change in the disposition through which the child, although bright and lively before, suddenly becomes listless, or excessively emotional, a condition which may continue for several weeks. There are irregularity of the pupils and pulse, a sharp "cephalic" cry, severe headache, insensibility to light and sound, grinding of teeth, a flushed face in paroxysms, usually before convulsions, rolling and drawing back of head, urine scanty and high-colored, oscillation of the eyes, obstinate constipation, etc. With coma comes strabismus; the pupils do not contract under the influence of light, but will contract and expand when the bowels rumble or the patient is moved. There are convulsions, paralysis and automatic movements of the feet and hands, it may be for hours. The thumb may be turned in. There is a hollowed abdomen (boat-shaped) and congestion of the eyes, a puri form secretion sticking the eyelids together; involuntary discharge of bowels and bladder, are common. For treatment of this affection place patient in bed, in a quiet room; give easily digested food; apply an ice-cap to the head and warmth to the feet. Further treatment should be in the hands of a physician. Much can be done by parents and guardians to prevent the onset, by not developing the nervous system at the expense of the muscular and digestive systems. Precocious children are to be judiciously restrained, and outdoor life encouraged. Tuberculous meningitis in adults is commoner in men than in women, and most frequently occurs between 17 and 30. It is generally fatal in 2 to 14 days, about one in 200 cases recovering.

Spinal meningitis is not common; it is usually caused by infection, is liable to occur in children with spina bifida and is rarely amenable to treatment. Death occurs usually in from eight to 10 days, either from extension of inflammation to the brain and pressure there by fluid, or from asphxyia due to spasms of the respiratory muscles. The lesions are similar to those of cerebral meningitis. The chief symptoms are pain in the spine and extremities, increased by movements

of the body, great sensibility of the surface of the body, spasms of muscles, opisthotonos and dyspnœa.

Epidemic cerebro-spinal meningitis, or spotted fever, is due to a special micro-organism, the *diplococcus intra-cellularis*. Death frequently occurs in a few hours; recovery usually requires 30 or more days. The disease has spread over sections of this country two or three times, mainly in the winter and spring. The exact manner of its transmission is not known. One form is characterized by fever with no eruption; the other by fever and an eruption. The symptoms are a chill or chilliness, followed by nausea and vomiting, fever, violent headache, sometimes with pain down the spinal column, general hyperæsthesia, great prostration, vertigo, tetanic rigidity of muscles, irritability or apathy, delirium and other symptoms of meningeal irritation, followed more or less rapidly by those of coma. In the majority of patients if the head is raised when the patient is lying on his back, the knees are involuntarily flexed. When there is an eruption it usually appears early and consists of dark blotches, from the size of a pinhead to that of a nickel, and is not marked on the extremities.

Where death occurs within 12 hours from the time of attack only a congestion of blood-vessels of the brain and, it may be, of the spinal cord, is generally found. Almost always there is lymph or pus beneath the pia mater, and sometimes serous effusion in the pleura, pericardium or peritoneum. The blood undergoes a change, ecchymoses are found sometimes in the muscles, or in connection with the pericardium or pleura. This disease is treated with a serum, which was first produced in the monkey but now is successfully derived from the horse. The serum is given in frequent doses depending on the severity of the case, from 12 to 24 hours apart; this treatment has reduced the mortality to 30 per cent. In the chronic variety serum therapy is of no avail; the application of cold to the head should depend upon the desires of the patient. Pain has to be controlled by morphine. Sulfanilamide and related compounds have helped many of the patients with infectious meningitis.

SMITH ELY JELLIFFE, M.D.

MENIPPUS, mĕ-nĭp'ŭs, Greek cynic philosopher, a native of Gadara in Palestine, and supposed to have flourished about 260 B.C. His writings were chiefly of a satirical kind. Lucian styles him "the most snarling of cynics," and in two or three of his dialogues introduces him as the vehicle of his own sarcasms. It appears that his satires were composed in verse and prose, on which account those of Varro were denominated Menippean, and for the same reason the name of Satire Ménippée was given in France to the celebrated piece written against the League and Philip II of Spain, its head. His writings are lost.

MENKEN, Adah Isaacs (originally DOLORES ADIOS FUERTES), American actress: b. near New Orleans, La., 15 June 1835; d. Paris, France, 10 Aug. 1868. Making her début with her sister as danseuses, at the New Orleans French Opera House, she was received with marked favor and visited Cuba, Texas and Mexico. On her return to New Orleans, she published a volume of verse and taught French and Latin at a girls' academy in that city. In 1858 she appeared in 'Fazio' in New Orleans, and went to England in 1863–64, assuming the rôle of Mazeppa at Astley's which won her popularity. After 30 Dec. 1866 she played in Paris for 100 nights, and later in Vienna and London. Her last appearance was in Paris in May 1868. She was famous for her fine form, and many marriages and divorces; Alexander I. Menken, John C. Heenan, J. H. Newell and James Barcley being her successive husbands. Her mind seems to have been as winning as her physical beauty, for among her friends were numbered Charles Reade, Dickens, Swinburne and the elder Dumas.

MENNO SIMONS, Dutch religious reformer: b. Witmarsum, Friesland, 1492; d. Oldesloe, Holstein, 19 Jan. 1559. He was ordained priest in the Roman Catholic Church and took pastoral work in the village of Pingium (1524), and from a study of the New Testament, undertaken (1530) to solve his doubts about transubstantiation, he was induced to become an evangelical preacher and finally left the church of his ordination. The martyrdom of Sicke Snyder at Leeuwarden for Anabaptism impelled him to consider the Scriptural grounds for infant baptism. He was finally converted to the cause of the Anabaptists, but never sympathized with the excesses of Münzer and wrote a diatribe against John of Leyden (1535). In 1537 at the request of a number of Anabaptists of Groningen he assumed the functions of an Anabaptist preacher and exercised, by his moderation, a most salutary influence on his fellow-ministers. He now married, his change in faith having superseded his vow of celibacy, and began to travel as an evangelist not only in Friesland but throughout Holland and Germany as far as to Livonia. Being persecuted from place to place he finally settled in Oldesloe in Holstein, where he closed his ministry with the consciousness of having founded a large and flourishing sect, whose subsequent history is related under the title Mennonites (q.v.)

Views of Menno Simons.—Menno was rather a preacher of a system of personal sanctity than either a dogmatist or a violent fanatic like some of the Anabaptists. He was a man of pure moral and devotional enthusiasm, whose account of his own conversion reads like a passage from the 'Confessions' of Augustine. He sums up the results of his labors as consisting in the conversion and recovery of the wicked. Yet he formulated a somewhat vague profession of faith. He believed in the divinity of Christ, who was born on earth *in* Mary, that is without taking upon him human flesh and blood. He rejected infant baptism, and baptized those only who made a personal profession of faith in Christ. He particularly emphasized the power of excommunication possessed by the Church, without which "the spiritual Kingdom of God on earth cannot," he said, "exist in purity and piety." He believed in the coming millennium (q.v.); he excluded civil magistrates from church membership on the ground that the church was a theocracy whose magistrates were the ministers. He declared that war and all taking and administering of oaths were unlawful, and re-

garded human science as useless, even pernicious to a Christian. These decrees, however, as modified by the explanations of Menno, differed little from those generally promulgated by the Reformed bodies of his day. His principal teaching was of a moral and practical character. He was a meek, humble, noble-minded man, carried away with the spirit of his times, encouraging all that was good and pure among his followers, and sternly rebuking the guilty. The best edition of his work is 'Opera Omnia Theologica of al de Godgeleerde werken vann Menno Simonis' (1681). Consult Harder, 'Leben Menno Simons' (1846); Roosen, 'Menno Simons den evangelischen Mennonitengemeinden geschildert' (1848).

MENNONITES, a body consisting of a dozen or more branches of followers of Menno Simons, akin to Baptists in faith and practice: Menno Simons (1492–1559), a Holland Anabaptist, was not the founder of the body that bears his name, but was a convert to it several years after it began, and became its chief leader and author. He early left the priesthood of the Roman Catholic Church, espousing the views of the Anabaptists, but opposing the fanatical extremists of Münster. His books were his chief contribution to the movement, which really grew out of the division of Protestantism which is called by the name Anabaptist. The Anabaptists were opposed to the baptism of infants, baptizing only on confession of faith. The followers of Menno Simons became numerous in Holland, Germany and Switzerland, and thousands were persecuted to death, particularly in Holland, because of their views in regard to the temporal power. Rising in the first half of the 16th century (they were first called Mennonites in 1550, though the name was never generally adopted in Europe as it was in America) they increased under persecution and emigrated to Russia and the United States to escape it — to the former country near the close of the 18th century and to the latter from 1640 on, coming from Holland, and Germany to New York and New Jersey. They were drawn to Pennsylvania by William Penn's announcement that those settling in that colony would enjoy freedom in the practice of their religious faith. The Society of Friends in England assisted the Mennonites of Holland to emigrate. The first Mennonite colony was formed at Germantown, near Philadelphia, in 1683. Thence they spread to Lancaster, Bucks, Berks and other counties in Pennsylvania and from that State to other States and to the Canadian provinces. They came in constant contact, in colonial and post-colonial days, with the Indians, but like the Friends, being opposed to bearing arms and inclined to peace they suffered little from attacks by the savages. It is worthy of note that a Mennonite meeting at Germantown as early as 1688 adopted a protest against the traffic in slaves, saying that those «who steal or rob men and those who buy or purchase them» are all alike.

Though Mennonites are widely divided among themselves on questions of practice and principle, they are in substantial agreement in holding doctrines of the evangelical type, as expressed in a declaration of faith adopted at Dort, Holland, in 1632, which confession is generally accepted by the Mennonites of America. They adhere to the principles of autonomy of the churches, freedom of conscience, separation of church and state, adult baptism, non-resistance and practical piety. Baptism is administered on confession of faith, not by immersion, but by pouring, the candidate either kneeling or standing in water and the minister taking up water in both hands and pouring it upon the head, using the scriptural formula. In the ministry there are bishops, or elders, ministers, who are pastors or evangelists, and deacons, who are almoners and assist in administering the ordinances and take charge of congregations in the absence of bishop or minister. Ministers are selected by members of the church, who go one by one to a private room for the purpose. If more than one are thus selected choice between them is made by lot. A bishop has charge of all the churches in his particular district and ordains the ministers and deacons. He is selected in like manner as ministers and deacons. The Lord's Supper is observed twice a year, in the spring and in the fall, preceded by an examination of each member in faith and standing, and followed by the ceremony of feet-washing and the kiss of peace, the sexes separating for this purpose.

Mennonites are opposed to the judicial oath and many practise non-conformity to the world. Their polity provides for the autonomy of the churches, but appeals are taken to the conference. Decisions of conference are submitted to the churches for approval.

The 12 or more branches in America differ so little in some instances that it is difficult to distinguish between them except by name. The census of 1916 reported three bodies in the group not in existence, or not known, in 1906. The distinctive bodies are: (1) Mennonite Church; (2) Conservative Amish; (3) Old Order Amish; (4) Church of God in Christ; (5) Old Order Mennonite (Wisler); (6) Reformed Mennonite; (7) General Conference of Mennonites; (8) Defenceless Mennonites; (9) Mennonite Brethren in Christ; (10) Mennonite Brethren Church; (11) Krimmer Brueder Gemeinde; (12) Hutterian Brethren. There are besides small unattached bodies which may be grouped as miscellaneous, including the Kleine Gemeinde, Stauffer Mennonites, etc.

A historical distinction, which also marks a difference in doctrinal position, may be traced between two European groups and through their descendants in America: (1) Those of Holland, Switzerland and northwestern Germany, and (2) those of Prussia, North Germany and Russia. These emigrated from Holland and used the Dutch tongue until after the middle of the 18th century, when they adopted the German which they still employ. They are of the orthodox type. The first group became liberal or rationalistic and are not in fellowship with the representatives of the second group.

1. Mennonite Church.— This is the largest and oldest body of this faith in America. It is descended from the colony which settled in Germantown. In tendency it occupies middle ground between the stricter and the more liberal schools. Since 1896 it has had a biennial General Conference, composed of dele-

gates elected by the State conferences. The Amish body is represented in this conference—the two churches are practically one—and cooperates in the conduct of the general missionary, educational and benevolent work. The board of missions has missionaries in India and in America, with a department of city missions. The chief educational institution is at Goshen, Ind. In 1936 the total membership in Mennonite Church organizations (17 in number), was 116,655. This number included about 1,600 members under the age of 13 years. The number of ministers in all of the bodies was 1,752, who served 1,001 churches. The membership is largest in Pennsylvania and Ohio with representation in other mid-western States and in the South. *The Mennonite,* of Berne, Ind., is published in the English language and another paper printed in German is published at the same place.

2. Conservative Amish Mennonite Church.—This is a small body of the Amish type which has churches in Pennsylvania, Illinois, Ohio and Canada. The membership in 1936 totaled 2,281 served by 38 ministers in 18 congregations. The churches were combined in a single conference. The Amish settlement in Canada was founded in 1824 in Wilmot Township, Ontario, on land given by Christian Nafziger of Munich. The Amish Mennonites date from 1690, separating from the Mennonites in Switzerland and Alsace on account of their laxness of discipline. The name is derived from Jacob Ammon or Amen, who insisted that the doctrines set forth in the Dort Confession of Faith should be interpreted literally and accepted strictly. In late years this strictness has been relaxed and the main body of Amish is practically reunited with the Old Mennonites in the Mennonite Church.

3. Old Order Amish Mennonite Church.—This body represents the stricter descendants of Jacob Amen and the Swiss Amish of the 18th century. While the main body of Amish were approaching agreement with the main body of Mennonites, the stricter wing were holding the older position resulting in the organization in 1865 of the Old Order Church. This body is opposed to building churches, holding that one place is as sacred as any other and that separate church buildings savor of ritualism. They therefore hold their meetings in private houses, which necessarily makes their congregations small. A Sunday service usually continues about four hours, and is exclusively in German. They use the old hymnal, *Aus bund,* first published for the Swiss brethren in 1571 and reprinted many times in America. The tunes supposed to be the original have never been committed to musical notation and of course never printed. The sermon is without text, and traces God's dealing with the race from Adam down, setting forth the sinfulness of sin and God's love and care for his obedient children. On communion Sundays services are continued from morning till night without intermission, several ministers being in attendance to keep them going. There is no church property, except hymnbooks, plain benches and utensils necessary to the preparation of a plain dinner. Houses and clothing of families, who observe a sort of community life, are very plain, carpets, curtains and wall pictures being forbidden. They have a few Sunday schools and no missionary or benevolent societies, schools or periodicals. They use the ban in discipline, following the example of the original Amish, who in some cases use the extreme penalty of separation of husband and wife. The person against whom the ban was pronounced was cut off from social and family intercourse with all members of the church and was treated as an outcast. The census of 1936 credits the Old Order Amish Church with 8,600 members, an increase of nearly 3,000 in 10 years, 127 churches and 355 ministers.

4. Church of God in Christ.—A small body of reformers, led by John Holdeman who insisted that the Mennonite Church had forsaken its original foundations. It originated in Ohio in 1859. Holdeman revived the ban as formerly observed in Europe. The body had subsequently considerable accessions of Russian Mennonites, under whose influence the stricter views were gradually relaxed. The census of 1936 credits this body with 50 ministers, 26 churches, and 2,100 members. There has been little change in the first two items since 1906, but the number of members was doubled.

5. Old Order Mennonite Church (Wisler).—Jacob Wisler led a movement in opposition to innovations, such as revival meetings, Sunday schools, etc., which resulted in the organization, in 1870, of the Old Order Church. Other small bodies in Canada, Virginia and elsewhere, which occupied a similar position, joined with the Wisler movement, which holds strictly to the Dort Confession of Faith. The Church has 37 ministers, 23 churches and 1,848 members (census of 1936), each item indicating little change since 1906.

6. Reformed Mennonite Church.—This branch is also the result of a reform movement toward stricter regard for doctrine and discipline, led by Francis Herr and his son John. The Herrites have no fellowship whatever with other churches, and conduct no Sunday schools or missions. They are decreasing in number. In 1936 they had 25 ministers, 23 churches and 1,040 members, mostly in Pennsylvania.

7. General Conference of Mennonites in North America.—An attempt to unite various Mennonite bodies holding practically the same doctrinal views and observing the same practices, resulted in a general conference in Iowa, in 1860, and the organization of this body. Groups of Russian and German churches subsequently joined with it. It is active in missionary and educational work. There are boards of home missions, of foreign missions, of publication, of education and of emergency relief. Three colleges are maintained at Newton, Kan., Bluffton, Ohio, and Freeman, S. D. Several periodicals, including *The Mennonite,* weekly, are published at Berne, Ind. The General Conference accepts the Dort Confession, but does not observe the foot-washing ceremony in connection with the Lord's Supper, nor does it require the women to have a head covering during prayers and worship. Its platform of union is acceptance of the Dort Confession, salvation by grace through faith in Christ, baptism on confession of faith, refusal to take oaths, peace, non-resistance and practice of scriptural discipline. The General Conference, which is gaining in numbers, has, according to the census of 1936, 238 ministers, 138 churches and 25,780 members.

8. Mennonite Brethren in Christ.—This branch grew out of an evangelistic effort in Pennsylvania, in 1853. The first conference was formed in 1858. The movement spread and three groups came into existence, which united in 1879; subsequently other groups joined the body which took its present form and name in 1883. There is a general conference which meets every four years, and five district conferences in the United States and two in Canada. A weekly newspaper, *The Gospel Banner,* is published in New Carlisle, Ohio. The General Conference has 125 ministers, 125 churches and 9,000 members.

9. Defenceless Mennonite Church.—A small body of 1,500 members, which insists upon a definite experience of conversion, organized under the leadership of Henry Egli, in 1860, an offshoot of the Amish branch. It has a mission in Africa and is akin to the conference of Defenceless Mennonites known, until recently, as the Minnesota and Nebraska Conference of Mennonites and now affiliating with the Mennonite Church. (See 1. *Mennonite Church, supra.*)

10. Mennonite Brethren Church.—This body, which was not reported by the census of 1906, has three district conferences in the United States and one in Canada. It conducts home and foreign missions and has a college at Hillsboro, Kans., where it publishes the *Zion's Bote.* The census of 1936 gives this church 201 ministers, 62 churches and 8,200 members.

11. Krimmer Brueder Gemeinde.—A union of two bodies of Brueder Gemeinde, which came originally from Russia, where they separated from the main body of Mennonites, because they were thought to be lax in religious life and discipline. They differ from other Mennonites in baptizing by immersion and not by pouring, and they formerly differed among themselves as to the mode, one group baptizing with a forward, the other with a backward movement. There are 1,852 members, with 32 ministers and 16 churches.

12. Hutterian Brethren.—These are descendants of the Hutter Brethren of South Russia. Their leader was Jacob Hutter, who was burned at the stake at Innsbruck, in the Tyrol, in 1536. The Hutterian Brethren are not strictly Mennonites, but agree with them and are so classed. They formerly observed community life in South Dakota, and have sometimes been called Bruederhoef Mennonites. They have (census of 1936) 926 members, with 31 ministers and 12 churches.

The *Kleine Gemeinde,* the *Stauffer Mennonites* and the *Central Conference* are small groups, differing in minor particulars among themselves and from other Mennonite bodies. The Central Conference in 1936 had a membership of 4,500 in 25 churches served by 32 ministers. Membership in all of the Mennonite bodies is highest in Pennsylvania.

Consult Smith, C. H., *The Story of the Mennonites* (Berne, Ind. 1940); Klein, H. M. J., *History and Customs of the Amish* (York, Pa. 1946); Wenger, J. C., *Glimpses of Mennonite History* (Scottdale, Pa., 2d ed., 1947); *Mennonite Yearbook and Directory,* published annually (Scottdale, Pa.). HENRY K. CARROLL, *Author of "Religious Forces in the United States."*

MENOCAL, Aniceto Garcia, American civil engineer: b. Cuba, Sept. 1, 1836; d. New York City, July 20, 1908. He was educated in Havana and was graduated from the Rensselaer Polytechnic Institute in 1862. In 1863–1869 he was engaged as sub-chief engineer of the Havana waterworks and in 1870 returned to New York, where he was two years in the engineering branch of the waterworks department. He was chief engineer of all the surveys made for the Isthmian Canal by the United States government and was sent to Paris in 1879 as member of the Canal Congress He was a member of several scientific societies and published many of his official reports.

MENOMINEE, the French FOLLES AVOINES, a tribe of North American Indians of Algonquian stock, formerly known in upper Michigan and Wisconsin, along the Menominee River and Green Bay, and ranging west to the Mississippi and south to the Fox River. Their name signifying "wild-rice men," hence the French translation is derived from their use as a staple food of the abundant wild rice of the region. Their descendants numbering about 1,890, civilized and Roman Catholics, inhabit Keshena Reservation, Wisconsin.

MENOMINEE, mē-nŏm'ĭ-nē, city, Michigan, Menominee County seat, altitude 581 feet, at the mouth of Menominee River, on Green Bay, an arm of Lake Michigan; on the Chicago, Milwaukee, St. Paul and Pacific, and the Chicago and North Western railroads; opposite Marinette, Wis., and 100 miles in direct line south of Marquette, 46 miles northeast of the city of Green Bay, Wis. It has car-ferry service to Frankfort, across the bay and lake, steamboat connections with lake ports, and is a port of entry. It has a county airport.

Situated in an extensive lumbering region, industries include some having connection with lumbering, as the manufacture of furniture. Machinery, electrical goods, limestone products, beet sugar, meat products, beer, and paper are important manufactures. The industrial payroll in the city's industries runs to about $25,000,000 annually.

The city has a public library and a hospital. Settled in 1799, Menominee received its city charter in 1883. It has a mayor and council form of government. Pop. (1930) 10,320; (1940) 10,230; (1950) 11,107.

MENOMONIE, city, Wisconsin, Dunn County seat, altitude 807 feet, on the Red Cedar River, the Chicago, Milwaukee, St. Paul and Pacific, and the Chicago and North Western railroads, and on state and federal highways; 26 miles by rail west of Eau Claire. Formerly it was an important lumbering center, and now processes dairy products, flour, and feed. Its principal industrial output is Parker pen products. There are brickyards.

The public library is the Mabel Tainter Memorial. The city is the seat of Stout Institute, a state teachers' college since 1911. Settled in the 1840's, Menomonie received its city charter in 1882. It has a mayor, six councilmen, and a superintendent of public works. Pop. (1940) 6,582; (1950) 8,245.

MENOPAUSE, the cessation of menstrual flow in women; climacteric. This epoch is reached generally between the 45th and 52d years,

and is frequently marked by nervous disturbances. The power of child-bearing terminates at the menopause. It is popularly termed the "change of life." A woman who begins child-bearing early and gives birth to a large family usually has her menopause earlier than a childless woman. The approach of the menopause is marked by irregular—usually delayed—menstruation, and sometimes the latter flows are very profuse and weakening. See CLIMACTERIC.

MENOPOME, a giant salamander of the genus *Cryptobranchus* (formerly *Menopoma*). See HELLBENDER.

MENOTTI, mā-nôt'tē, **Gian-Carlo** jän-kär'lō, Italian composer and dramatist: b. Cadegliano, near Milan, July 7, 1911. At the age of eleven, he had written his first opera, *The Death of Pierrot,* and, along with the other nine children, participated in the family chamber music group. He attended the Milan Conservatory for two years and in 1928 came to the United States to study at Curtis Institute under Rosario Scalero. In 1933 he began work on the libretto and music for *Amelia Goes to the Ball* which was successfully produced at the Philadelphia Academy of Music in 1937 and at the Metropolitan Opera House the following year. The National Broadcasting Company commissioned him to write an opera for radio, *The Old Maid and the Thief,* which was presented in 1939. Among his other works are *The Island God,* another opera produced at the Metropolitan; *The Telephone* (q.v.), a burlesque of the Donizetti style which despite a melodic eclecticism developed a creative style of its own; *The Medium* (q.v.), a contemporary example of verism; *Sebastian,* a ballet; *Errand Into the Maze,* a ballet produced by Martha Graham; a Piano Concerto; a Pastorale for string orchestra; and *Variations on a Theme of Robert Schumann* which won the Lauber Musical Award in 1931. In 1946 he began work on another comic opera, *The Last Superman,* after winning the Guggenheim Fellowship award of $2,500. In the summer of 1947, he directed his own play, *A Copy of Madame Aupic,* at New Milford, Conn.

MENPES, Mortimer, English artist: b. Adelaide, South Australia, 1859; d. April 1, 1938. He went to London when 19, studied at South Kensington; spent three years in Brittany at Pont Aven; traveled throughout Europe, Asia, and Mexico; and wherever he went continued his early experiments in color and his attempts to reproduce the atmosphere of various localities. He revived the lost art of printing in color from etched plates; made some excellent dry point etchings, notably one of Hals' *Archers of Saint Adrian.* During 1900 he was war correspondent in Africa for *Black and White.* He also supervised the reproduction of *The Menpes Series of Great Masters.* Among his publications are *War Impressions* (1901); *World Pictures* (1902); *The Durbar* (1903); *Whistler as I Knew Him* (1904); *India* (1905); and *Sir Henry Irving* and *Thames* (1906).

MENSA, or **MONS,** *in astronomy,* one of the 14 constellations which Lacaille discovered at the Cape of Good Hope. It is named from the mountain which is a conspicuous feature of the landscape at the Cape. The constellation is a very inconspicuous one near the South Pole, its brightest star being only of 5.3 magnitude.

MENSTRUATION, the periodical discharge of the menses or bloody fluid from the female generative organs. In women it normally occurs at intervals of one lunar month, or 13 times a year (hence the use of the term *menses,* Latin plural of *mensis,* month). Its first appearance marks the stage of puberty, and is usually attended by definite changes—enlargement of the breasts, showing development of the mammary glands, growth of the ovaries, of the uterus and external genital organs, etc., and by other signs, physical and mental, of approaching womanhood and maturity. It usually begins in temperate climes between the 13th and 15th year; in hot climates it is apt to commence as young as 12 years, and in very cold climates as late as 17 years; its periodic recurrences continue until the menopause (q.v.) or final cessation of the discharge, which ordinarily arrives somewhere between the 45th and 52d years. The recurrent periods of its appearance, as well as their duration, vary with different females, and not infrequently in the same individual; the variations, however, not always indicating abnormal or pathological causes. The immediate cause of menstruation is the breaking away of an ova or egg from one of the ovaries. (See OVARY). Menstruation is often at first, and in many persons throughout the catamenial age, attended by characteristic pains and symptoms, with physiological and psychological conditions of disturbance or depression, which sometimes call for special hygienic treatment. During pregnancy (with exceptional cases) there is no menstrual flow, its cessation being one of the earliest signs of conception. Observance of wholesome rules of exercise, rest, etc., helps to maintain normal conditions of body and mind, the reverse of which, owing to neglect of such rules, so often makes the menstrual function a visitation of dread and distress.

Disorders of Menstruation.—These include amenorrhoea, dysmenorrhoea, menorrhagia and metrorrhagia. Amenorrhea is an absence of the menstrual flow from some cause other than pregnancy or the approach of the menopause (q.v.) or tardy establishment of the menstrual function. It is a symptom of anemia (q.v.), or may be due to a constitutional condition such as profound nerve-fag or tuberculosis. Strychnine, iron and ergot may be administered internally or the physician may apply local treatment. (See DYSMENORRHOEA). Menorrhagia is an abnormally profuse flow during the menstrual period, due to one of several conditions. If not checked by rest, a physician is necessary, as also in metrorrhagia, which is a sanguineous flow between the menstrual periods.

MENSURAL MUSIC. Mensural or measured music is a term applied to a historical style of composition in which the tones bore exact relations to each other in regard to length or time. Such a designation and the occasion for it may appear strange, as precise rhythm seems to belong to the essence of music. This, however, is not the case; there was a period when notes were not exactly measured, and mensural music is a subsequent development from this early practice.

All European music of a higher character

was originally cultivated in connection with speech or poetry. This is true of the music of the Greeks as well as the early Christians. But speech is not necessarily rhythmical. Ordinary speech is not so at all, and even poetry is not always characterized by the exact time relations typical of strictly measured music. A trochee can be delivered either in two or three part time, the accented syllable matching the unaccented in duration or requiring double as much time. And in impassioned utterance rhythmical relations are apt to be lost sight of altogether. Moreover, any rhythm which the accompanying tones may possess would be theirs only by virtue of the words to which they are added: it would be a rhythm of the poetry, not of the music.

Such was the case in Greek music. Although instrumental performances were also in vogue among the Greeks, music with them, as we have said, was primarily vocal. We know little of its exact character, but are probably justified in regarding it as a species of recitative, the words guiding the course of the tones. In Christian times the earliest fixed type of the art was the Ambrosian chant, formulated by Saint Ambrose of Milan in the 4th century. This, too, was similar to Greek music in its adherence to the rhythm of the words. A change was wrought by Pope Gregory the Great, two centuries later. What distinguishes his chant from the Ambrosian is supposed to be the uniform length of its tones, giving it a character similar to that of our choral. However, this is probably true only in part. According to the historian Ambros, the sections of the chant which were sung by many voices may have been measured and regular, but the utterances of the priest must have retained much rhythmical variety. The real difference is formulated by him as follows: "The Ambrosian chant was based essentially on the poetical metre, the Gregorian on the musical." Whatever the exact nature of the difference, however, there is no doubt that Gregory effected a liberation of the tones from the rhythmical shackles of the words. And this was a gain of far-reaching importance. Music had now won its independence, and the way was prepared for the development of mensural composition.

The more immediate occasion for this development was the introduction of harmony. Just as music had primarily been vocal, so also it had been unisonal in character. Though a second tone may occasionally have been added to the principal part, nothing like the later polyphony was attempted. In the 9th century, however, the so-called Organum of Hucbald makes its appearance. In this the theme is systematically accompanied by one, two or three other voices, singing intervals of a fourth, fifth and octave in parallel motion. The point was now reached beyond which no further advance was possible without an exact designation of the length of the notes. As long as the singing had been confined to a single person this was not necessary. Nor was it necessary in the case of several persons chanting in unison, if the length of the notes was regulated by the natural accent of the words, or if all the tones were of equal length. In the Organum, however, a certain care was already required. The singers had to stand so that they could see as well as hear each other, and one among them acted as leader, introducing the new notes at the proper moment. The Organum now developed in various directions. There was a more independent progression of parts, contrary alternating with parallel motion, and the tones no longer coincided with each other note for note, but one voice sang two or more tones while the other sang one. Manifestly this required an understanding as to the relative duration of the tones, and a method of designating the differences graphically. The first person to formulate the solution of this problem was Franco of Cologne, who lived about the year 1200. Previous to him tones of two lengths, the longa and brevis, had already been recognized. He also admitted the duplex longa or maxima,—twice as long as the longa, and the semi-brevis,—half as long as the brevis. The notes in question were represented as follows:

Rests were also indicated by Franco, by means of appropriate signs. The bar-line was not yet in use, but measure was recognized, being at first confined to triple or "perfect" time. Duple or "imperfect" time was only permitted at a later date.

There were many complexities in the system as promulgated by Franco and his followers. Thus the length of the notes was not only determined by their own character and appearance, but also depended on the neighboring notes. There were "alterations" and "imperfections," "prolations" and "ligatures," but space will not permit us to enter into all these involved details, which have only a remote historical interest. The rules governing mensural music were further elaborated—among other writers—by Marchettus of Padua, who lived about a century after Franco; and Jean de Muris, a celebrated theoretician of the 14th century. Notes of shorter duration were gradually introduced, such as the minima, semiminima, fusa and semi-fusa. And the notation too was modified, until it finally assumed the appearance to which we are accustomed to-day. Together with the Organum, mensural music furnished the basis for all subsequent advances in the art. It was the indispensable prerequisite for the growth of rhythmical and contrapuntal variety. It made possible the wonderful development in part writing which was soon to take place in the Netherlands, and which was eventually to lead to the glories of modern instrumental and choral music. In fine, it may be regarded as one of the two or three great elementary contributions to the art, on which the dazzling superstructure of modern beauty and inspiration has been erected.

ALBERT GEHRING,
Author of 'The Basis of Musical Pleasure,' etc.

MENSURATION. Mensuration is that branch of applied mathematics which treats of the metrical relations of geometric figures, in particular of the length of lines, the magnitude of plane and solid angles, the area of surfaces and the volume of solids. The term is used both for the act and for the art of measuring geometric magnitudes. Mensuration is not usually treated as a separate branch of mathe-

matics, but occurs as an integral part of various subjects, such as plane geometry, solid geometry, trigonometry and integral calculus. For a discussion of the measurement of plane, diedral, spherical and solid angles and of the relations between the sides and angles of a triangle (plane or spherical) the reader is referred to the article on TRIGONOMETRY. The present article will give formulas for lengths, areas and volumes of the simpler and the regular figures and methods of approximation for the more complex or irregular figures.

The measure of a geometric magnitude is its ratio to a fixed magnitude of the same kind selected as the unit of measurement. Throughout this article the unit of area is assumed to be a square each side of which is equal to the unit of length, and the unit of volume is a cube whose edges are likewise of unit length. The purpose of a formula is to show how one of these numbers (ratios) may be found from certain others which are supposed to be known or obtainable. Thus formula (XIX) says that the ratio of the area of a circle to that of a square each side of which is a foot long (that is, the area of the circle measured in square feet) may be obtained by multiplying together the ratio of the circumference to the unit of length known as a foot, the ratio of the radius to the same unit of length, and the number ½. It is important to recognize that in using any formula the units must all be of the same system. The number of acres in a field cannot be found directly from formula (X) by multiplying together the number of rods in two adjacent sides: this would give the number of square rods in the field. Nor is the number of gallons in a barrel given by formula (LXV) when the radii are measured in feet or in inches, but the number of cubic feet or cubic inches, as the case may be. In order to change any measure from one system of units to another the following table may be found useful:

To change		Multiply by	Inverse
in.	to cm.	2.53998	.393704
ft.	to m.	.304797	3.28087
miles	to km.	1.60933	.621377
sq. in.	to sq. cm.	6.45148	.155003
sq. ft.	to sq. m.	.0929013	10.7641
sq. ft.	to acres.	.0000229568	43560.
sq. yds.	to acres.	.000206612	4840.
sq. miles	to acres.	640.	.0015625
cu. in.	to cu. cm.	16.3866	.0610254
cu. ft.	to litres.	28.3161	.0353156
cu. in.	to gallons.	.004329	231.
cu. cm.	to gallons.	.000264184	3785.238

[in.= inches, ft.= feet, yds.= yards, sq.= square, cu.= cubic, m.= meters, cm.= centimeters, km.= kilometers].

(For other multipliers see WEIGHTS AND MEASURES). The second column of figures serves to change the unit in the opposite way to that indicated by the rest of the table: thus to change meters to feet multiply the number of meters by 3.28087; for instance, 10 meters is equal to 32.8087 feet.

In many cases the computation of area or of volume may be accomplished most easily by mechanical means. For the measurement of the area of plane figures ingenious and effective instruments known as planimeters have been invented. Two historic instances are the finding by Galileo of an approximate value for the area of a cycloid by cutting it out of a sheet of copper and weighing the model, and the discovery by Archimedes of a fraud in Hiero's new crown through measuring its volume by submersing it in water and measuring the water displaced. To apply this last method, multiply the number of ounces of water by 1.73, or less accurately by $\frac{7}{4}$, and the result will be the number of cubic inches in the object; or, measure directly the volume of the water displaced.

LENGTH OF LINES.

Circle.— The *circumference* of a circle is equal to the diameter multiplied by

3.14159265358979323846264338328 . . . . . .

This constant is usually denoted by the Greek letter π (pī) and is approximately equal to

$$3\tfrac{1}{7}, \quad \tfrac{8\,5\,5}{1\,1\,3}, \quad \text{or} \quad 3.1416.$$

Use the first if an error of one two-thousandth of the final result may be neglected, and the last if an error of one four-hundred-thousandth is negligible.

The above theorem may be written

$$l = \pi d, \qquad = 2\pi r, \qquad \text{(I)}$$

where l = length of circumference, d = diameter and r = radius.

The length l of the arc AMB in Fig. 1, in which MD is the perpendicular at the middle point of the chord AB, AE is tangent to the circle at A or perpendicular to the radius OA, OE is perpendicular to AM, the chord of half the arc or the angle AOE is one-fourth of the angle AOB, may be found by any one of the formulas

$$l = \frac{\pi}{180} dr, \quad \frac{\pi}{180} = \frac{1}{57} \quad \text{(error about } \tfrac{1}{3\,0\,0}\text{)} \qquad \text{(II)}$$

$$l = c + \frac{8}{3}\frac{h^2}{c}, \qquad \text{(III)}$$

$$l = 2k + \tfrac{1}{3}(2k - c), \qquad \text{(IV)}$$

$$= \tfrac{1}{3}(8k - c),$$

$$l = t + s, \qquad \text{(V)}$$

in which d = number of degrees in the angle AOB, r = radius OA, c = chord AB, h = height MD, k = chord of half the arc AM, t = length

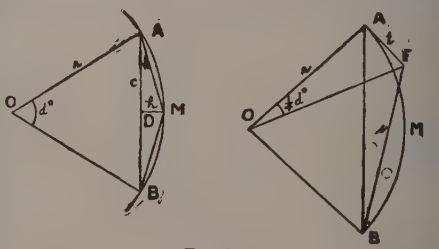

FIG. 1.

of AE, and s = length of BE. Formulas (III), (IV) and (V) are only approximate, the error being small only if the angle AOB or the ratio of h to c be small. Thus for an angle of d=90° the arc is 1.5708 . . . , whereas formulas (III), (IV) and (V) give 1.576 . . , 1.5696 . . , 1.5732 . . , respectively.

Parabola.—The length l of the arc AVB of the parabola in Fig. 2 is

$$l=\sqrt{y^2+4x^2}+\frac{y^2}{2x}\left(\log\frac{2x+\sqrt{y^2+4x^2}}{y}\right)\ldots, \quad \text{(VI)}$$

where $x=VD$, $y=AD$, and the logarithm is taken to the base e.

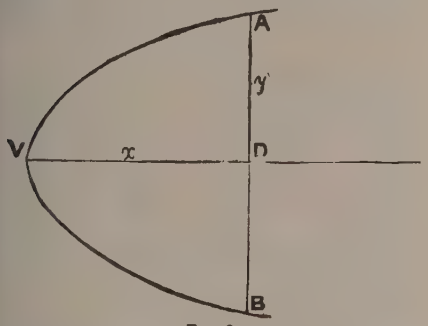

Fig. 2.

Ellipse.—The length l of the circumference $ABA'B'$ of ellipse in the next figure (Fig. 3), in which F and F' are the foci ($BF=BF'=OA$), is

$$l=2\pi a\left(1-\tfrac{1}{4}e^2-\tfrac{3}{64}e^4-\tfrac{5}{256}e^6\ldots\right), \quad \text{(VII)}$$

or approximately

$$l=\pi\sqrt{2(a^2+b^2)} \quad \text{(VIII)}$$
$$=4.443d;$$

where e is the eccentricity $\left(OF/OA=\frac{1}{a}\sqrt{a^2-b^2}\right)$; $a=OA$, one-half the longest diameter; $b=OB$, one-half the shortest diameter; $d=AB=\sqrt{a^2+b^2}$.

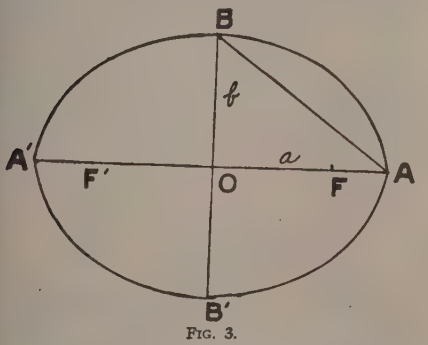

Fig. 3.

General Methods of Approximating the Length of Any Curved Line.—Divide the line into parts each of which differs but little

Fig. 4.

from a small circular arc. Then each portion may be found by any one of the formulas (III), (IV) or (V). A convenient method for the use of formula (IV) is indicated by the diagram herewith (Fig. 4) and formula (IX). The only restrictions upon the location of the points 1, 2, 3, 4, . . . in addition to that given above is that the odd-numbered ones must be half-way between the others and that there should be an odd number of points in all.

$$l=\overline{A1}+\overline{12}+\overline{23}+\ldots)+\tfrac{1}{3}[(\overline{A1}+\overline{12}+\overline{23}+\ldots)$$
$$-(\overline{A2}+\overline{24}+\overline{46}+\ldots)]. \quad \text{(IX)}$$

Area of Plane Figures.

Rectangle.—The area a of a rectangle, the lengths of two adjacent sides of which are b and c respectively, is

$$a=bc. \quad \text{(X)}$$

Triangle.—The area a of the triangle ABC (Fig. 5) is

$$a=\tfrac{1}{2}hb, \quad \text{(XI)}$$
$$a=\tfrac{1}{2}bc\sin A, \quad \text{(XII)}$$
$$a=\sqrt{s(s-a')(s-b)(s-c)}, \quad \text{(XIII)}$$

or

$$a=\tfrac{1}{2}b^2\frac{\sin A\cdot\sin C}{\sin(A+C)}; \quad \text{(XIV)}$$

where a', b, c are the lengths of the sides BC, CA, AB, respectively; h is the perpendicular distance (height) of B from AC; s is one-half of the sum of the sides: $s=\frac{1}{2}(a'+b+c)$.

If one angle of the triangle (say A) is a right angle, both formulas (XI) and (XII) simplify: namely, the era is one-half the product of the two sides which enclose the right angle ($a=\frac{1}{2}bc$). For a simple method of finding the area of an equilateral triangle ($a'=b=c$) multiply the square on one side by $\frac{13}{30}$ ($a=\frac{13}{30}b^2$, approximately), see formula (XVIII).

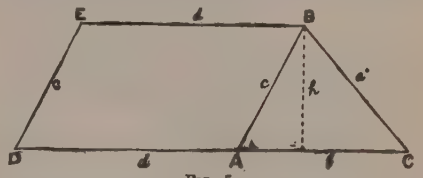

Fig. 5.

Parallelogram.—The area a of the parallelogram $ABED$ (Fig. 5) is

$$a=d\,.\,h, \quad \text{(XV)}$$

or

$$a=cd\sin D, \quad \text{(XVI)}$$

where c and d are the lengths of two adjacent sides, D is the angle between them, and h is the perpendicular distance between the two parallel sides whose length is d.

Trapezoid.—The area a of the trapezoid $CBED$ (Fig. 5), any four-sided figure with two of the opposite sides (BE and DC) parallel, is

$$a=\tfrac{1}{2}h(d+e), \quad \text{(XVII)}$$

where h is the perpendicular distance between the two parallel sides and d and e are the lengths of the parallel sides ($d=BE$, $e=DC$).

Regular Polygon.—The area a of a polygon bounded by n equal sides each of length s and having its n angles all equal is

$$a=s^2\times\frac{n\cot\frac{180^\circ}{n}}{4}. \quad \text{(XVIII)}$$

The following table gives (approximately) the value of the multiplier in the simpler cases:

NAME	n	$\frac{n \cot \frac{180°}{n}}{4}$.
Triangle	3	.433013
Square	4	1.
Pentagon	5	1.72048
Hexagon	6	2.59808
Heptagon	7	3.63391
Octagon	8	4.82843
Nonagon	9	6.18182
Decagon	10	7.69421
Undecagon	11	9.36564
Dodecagon	12	11.19615

Thus, for instance, if the side of a regular hexagon be 9 feet, its area is $81 \times 2.59808 = 210.4445$.

Irregular Polygon.— The area of an irregular polygon may be found by dividing it into parts each of which is a triangle, parallelogram, rectangle or trapezoid. Thus if we draw a system of parallel lines across the polygon, one through each vertex, each part will be a triangle or trapezoid and its area may be found by formulas (XI) or (XVI).

Circle.— The area a of a circle, whose radius is r and whose circumference is l, is

$$a = \tfrac{1}{2}lr, \qquad \text{(XIX)}$$

or $a = \pi r^2$. $\pi = 3.1416 = \frac{22}{7}$ (nearly). (XX)

The area a of the sector $OAMB$ (Fig. 1), in which l is the length of the arc AMB and d is number of degrees in the angle AOB, is

$$a = \tfrac{1}{2}lr, \qquad \text{(XXI)}$$

or $a = \frac{\pi}{90} dr$, $\frac{\pi}{90} = .034906585 = \frac{1}{28.6}$ (nearly).

The area a of the segment $AMBD$ (Fig. 1) is

$$a = \tfrac{1}{2}r(l - r \sin d°), \qquad \text{(XXII)}$$

$$a = \tfrac{2}{3}ch + \frac{h^3}{2c} \text{ (approximately)}, \qquad \text{(XXIII)}$$

or

$$a = \tfrac{2}{3}ch \text{ (approximately)}, \qquad \text{(XXIV)}$$

where r, l, c, h, d have the same meanings as in formulas (II), (III), (IV) and (V).

Parabola.— In Fig. 2 the area a of the segment $VABD$ with base $AB = 2y$ and height $VD = x$ is

$$a = \tfrac{4}{3}xy. \qquad \text{(XXV)}$$

Ellipse.— In Fig. 3 the total area a' of the ellipse $ABA'B'$, of which the length of the longest diameter $A'A$ is $2a$ and the length of the shortest diameter BB' is $2b$, is

$$a' = \pi ab, \quad \pi = 3.1416 \qquad \text{(XXVI)}$$

General Methods of Approximation.— Any plane area can be divided into parts each of which is a rectangle or differs from a rectangle in that one side is a simple curve as in Fig. 6. It is therefore sufficient to give methods by which an area, such as $ABB'A'$ following, may be measured.

1. The Trapezoidal Method.— Divide the base line AB into any number of equal parts, AP, PQ, QR, . . . , TB and erect the perpendiculars PP', QQ', . . . , TT'. Then if each portion $A'P'$, $P'Q'$, ... , $T'B'$ of the curve $A'B'$ is nearly coincident with its chord, the area a is

$$a = \overline{AP}[(\overline{PP'} + \overline{QQ'} + \overline{RR'} + \ldots + \overline{TT'}) + \tfrac{1}{2}(\overline{AA'} + \overline{BB'})]. \qquad \text{(XXVII)}$$

2. Simpson's Rule.— Divide the base line into any *even* number of parts (in Fig. 6 it is

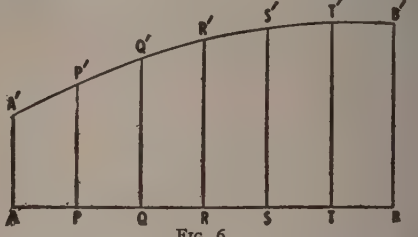

FIG. 6.

divided into six parts); erect the perpendiculars as before. Then

$$a = \tfrac{1}{3}\overline{AP}[\overline{AA'} + \overline{BB'} + 2(\overline{QQ'} + \overline{SS'} + \ldots) + 4(\overline{PP'} + \overline{RR'} + \overline{TT'} + \ldots)]. \qquad \text{(XXVIII)}$$

3. Weddle's Rule.— Divide the base into exactly *six* equal parts (as in Fig. 6), then

$$a = \tfrac{1}{10}\overline{AB}[5(\overline{PP'} + \overline{RR'} + \overline{TT'}) + \overline{RR'} + \overline{AA'} + \overline{QQ'} + \overline{SS'} + \overline{BB'}]. \qquad \text{(XXIX)}$$

SURFACE AND VOLUME OF SOLIDS.

Prism.— This includes any solid two of whose faces, known as the *bases*, are equal polygons situated in parallel planes and all the other faces, the *lateral* faces, are parallelograms. Thus in the following diagram (Fig. 7) the polygons ABC . . . and $A'B'C'$ . . . are the bases and the parallelograms $AA'B'B$, $BB'C'C$, . . . are the lateral faces. The edges AA', BB', CC', . . . are the lateral edges. The polygon UVW . . . lying in a plane perpendicular to one, and so to all, of the lateral edges is called a *right section*. The right section is equal to the base if and only if the lateral edges are perpendicular to the base.

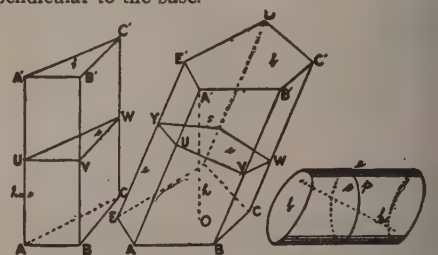

FIG. 7.

For the lateral area a which is the sum of the lateral faces $AA'B'B$, $BB'C'C$ . . . , and the volume v of a prism we have the formulas

$$a = e(\overline{UV} + \overline{VW} + \ldots), \qquad \text{(XXX)}$$

$$v = es, \qquad \text{(XXXI)}$$

$$v = hb, \qquad \text{(XXXII)}$$

in which e = length of a lateral edge (AA' or BB' . . .), s = area of a right section (UVW . . .), h = height, i.e., distance between bases, b = area of a base.

The volume v of a *truncated triangular prism*, that is one with three lateral faces and

whose bases are not parallel (therefore the lengths e_1, e_2, e_3 of the lateral edges not equal) is

$$v=\tfrac{1}{3}s(e_1+e_2+e_3). \qquad \text{(XXXIII)}$$

Any truncated prism may be divided into truncated triangular prisms and its volume thus found. For a four-sided prism whose opposite lateral faces are parallel this gives

$$v=\tfrac{1}{2}(e_1+e_2)s, \qquad \text{(XXXIV)}$$

where e_1, e_2 are a pair of opposite edges.

Cylinder.— This includes any solid having two *bases* which are equal plane figures bounded by curved lines (such as circles, ellipses or irregular figures), and situated in parallel planes, and the rest of the surface of the solid such that it may be thought of as consisting of an infinite number of parallel straight lines. If we call the length of each of these (equal) parallel lines e, the formulas for the prism given above (XXX, XXXI, XXXII) apply also to the cylinder, namely, the lateral area a and the volume v are

$$a=ep, \qquad \text{(XXXV)}$$
$$v=es, \qquad \text{(XXXVI)}$$
$$v=hb, \qquad \text{(XXXVII)}$$

where p is the length of the boundary, and s is the area of the section of the cylinder by a plane perpendicular to one of the lines lying on the lateral surface.

If the right section of a cylinder be a circle, the base, unless a circle, is an ellipse and its area is found by formula (XXVI). If in such a circular cylinder the bases are not parallel and the distance between the centres of the bases is l, then the area a and the volume v are

$$a=lp, \qquad \text{(XXXVIII)}$$
$$=2\pi rl, \qquad \text{(XXXIX)}$$
$$v=ls, \qquad \text{(XL)}$$
$$=\pi r^2 l, \quad \pi=3.1416, \qquad \text{(XLI)}$$

where r is the radius of the right section. These formulas are equivalent to (XXXV) and (XXXVI) when the bases are parallel, since then $l=e$.

Pyramid and Cone.— The volume v of any solid, such as those in Fig. 8, whose surface consists of a base, which is a plane figure of *any* kind, triangle, polygon, circle, ellipse, etc., and of triangles or curved areas which may be thought of as composed wholly of straight lines, joining the boundary of the base to some point (the vertex) not in the same plane as the base, is

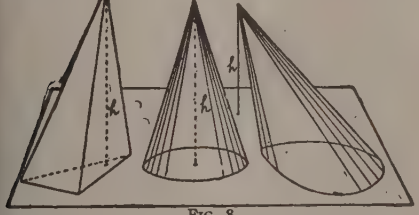

FIG. 8.

$$v=\tfrac{1}{3}bh, \qquad \text{(XLII)}$$

where b is the area of the base and h is the perpendicular distance (height) of the vertex from the plane of the base.

For a right circular cone, that is one in which the base is a circle and the line joining the vertex to the centre of the base is perpendicular to the plane of the base, the area a of the curved (lateral) surface is

$$a=\pi re, \quad \pi=3.1416 \qquad \text{(XLIII)}$$

where r is the radius of the base and e is the distance from the vertex to any point in the circumference of the base.

Prismatoid.— The volume v of any solid, whose total surface consists of two plane figures (the *bases*), of any character whatever, lying in parallel planes, and a lateral surface made up of triangles, trapezoids, or curved portions which may be thought as made up of straight lines joining the boundaries of the bases, is

$$v=\tfrac{1}{6}h(b_1+b_2+4m), \qquad \text{(XLIV)}$$

where h is perpendicular distance (height) between the bases, b_1 and b_2 are the areas of the bases, and m is the area of a section of the solid by a plane parallel to and half-way between the planes of the bases; or

$$v=\tfrac{1}{3}h(b+3q), \qquad \text{(XLV)}$$

where b is one of the bases and q is the area of a section parallel to and two-thirds of the way from, that base to the other.

Solids of Revolution. Sphere.— The area s of the surface and the volume v of a sphere of radius r are

$$s=4\pi r^2, \qquad 4\pi=12.56637\ldots \qquad \text{(XLVI)}$$
$$v=\frac{4\pi}{3}r^3, \qquad \frac{4\pi}{3}=4.18879\ldots \qquad \text{(XLVII)}$$

The volume v and lateral area a of a *segment* of a sphere (that is the part lying between two parallel planes) are

$$v=\frac{\pi}{6}h[h^2+3(r_1^2+r_2^2)], \quad \frac{\pi}{6}=.5236\ldots \qquad \text{(XLVIII)}$$
$$a=2\pi hr, \qquad \text{(XLIX)}$$

where h is the height of the zone (perpendicular distance between the parallel planes of the bases), r_1 and r_2 are the radii of the bases respectively, r is the radius of the sphere.

Spheroid.— For a *prolate* spheroid, that is the solid formed by revolving an ellipse about its longest diameter (in Fig. 3, about AA'), the area s of the surface and the volume v are

$$s=2\pi\left(b^2+\frac{ab}{e}\sin^{-1}e\right), \qquad \text{(L)}$$

or $$s=2\pi b(b+fa), \quad \text{(approximately)} \qquad \text{(LI)}$$

where a, b and e have the same significance as in (VII) and (VIII) and

$$f=1+\tfrac{1}{6}c+\tfrac{3}{40}c^2+\tfrac{5}{112}c^3+\tfrac{35}{1152}c^4+\tfrac{63}{2816}c^5+\ldots,$$

in which $c=1-\frac{b^2}{a^2}$. Or less accurately

$$s=\frac{\pi}{3}b\left[7a+b\left(6-\frac{b}{a}\right)\right], \quad \frac{\pi}{3}=1.0472; \qquad \text{(LII)}$$

$$v=\frac{4\pi}{3}ab^2, \quad \frac{4\pi}{3}=4.18879\ldots \qquad \text{(LIII)}$$

The volume v of a *segment* of a prolate spheroid (part cut off by a plane perpendicular to the axis of revolution) the height of which is h, is

$$v=\frac{\pi}{3}h^2\frac{b^2}{a^2}(3a-h), \quad \frac{\pi}{3}=1.047198\ldots \qquad \text{(LIV)}$$

For an *oblate* spheroid, that is the solid formed by revolving an ellipse about its short-

est diameter (in Fig. 3, about BB') the corresponding formulas are

$$s=\pi\left(2a^2+\frac{b^2}{e}\log\frac{1+e}{1-e}\right), \quad \text{(LV)}$$

or

$$s=2\pi(a^2+gb^2), \quad \text{(LVI)}$$

where

$$g=1+\tfrac{1}{3}d+\tfrac{1}{5}d^2+\tfrac{1}{7}d^3+\tfrac{1}{9}d^4+\tfrac{1}{11}d^5+\ldots,$$

in which

$$d=1-\frac{b^2}{a^2};$$

$$v=\frac{4\pi}{3}ba^2, \quad \frac{4\pi}{3}=4.18879\ldots \quad \text{(LVII)}$$

The volume v of a segment of an oblate spheroid is

$$v=\frac{\pi}{3}h^2\frac{a^2}{b^2}(3b-h). \quad \text{(LVIII)}$$

Paraboloid.— The volume v of the solid formed by revolving VAD in Fig. 2 about VD as an axis is

$$v=\frac{\pi}{2}xy^2, \quad \frac{\pi}{2}=1.5708\ldots, \quad \text{(LIX)}$$

which is just one-half the volume of the circumscribing cylinder.

The General Solid of Revolution.— The volume v of the solid formed by revolving any curve about a line lying in the same plane and not intersecting it, for instance by revolving $A'B'BA$ in Fig. 6 about AB as an axis, is

$$V=\frac{\pi}{3}.\overline{AP}[\overline{AA'}^2+\overline{BB'}^2+2(\overline{QQ'}^2+\overline{SS'}^2+\ldots)$$
$$+4(\overline{PP'}^2+\overline{RR'}^2+\ldots.)]. \quad \text{(LX)}$$

Or, as it is perhaps usually easier to measure the circumferences of the circles generated by PP', etc., than their diameters, if we denote the circumferences generated by A', P', Q'...., B' by a, p, q,..., b, respectively, the above formula may be written

$$v=\frac{1}{12\pi}.\overline{AP}[a^2+b^2+2(q^2+s^2+\ldots)+4(p^2+r^2+\ldots)],$$

$$\frac{1}{12\pi}=.0265258\ldots \quad \text{(LXI)}$$

The Regular Solids.— The area of the surface and the volume of the five regular solids may be found by means of the multipliers given in the following table:

NAME	Area = (edge)$^2\times$	Volume = (edge)$^3\times$
Tetrahedron	1.7320508	.1178511
Cube	6.	1.
Octahedron	3.4641016	.4714043
Dodecahedron	20.6457788	7.6631189
Icosahedron	8.6602540	2.1816950

(LXII)

General Method.— The volume of solids which do not come under any of the types treated above may be measured by an application of the prismatoidal formula (XLIV). Let $a_1, a_2, a_3, \ldots, a_{2n}, a_{2n+1}$ be the areas of a set of plane sections parallel to a suitably chosen base and dividing the solid into an even number ($2n$) of portions; a_1, a_{2n+1} being the end sections (that is, the solid lies wholly between a_1 and a_{2n+1}). The distance between consecutive cutting planes is to be the same throughout and to be taken so small that between the odd-numbered sections the solid is approximately a prismatoid. The area of a section may be found by surrounding it by a rectangle and measuring (by XXVII, XXVIII or XXIX) the portion of the rectangle outside of the section. If the distance between the sections be h, then

$$v=\tfrac{1}{12}h[a_1+a_{2n+1}+2(a_3+a_5+a_7\ldots+a_{2n-1})$$
$$+4(a_2+a_4+a_6\ldots+a_{2n})]. \quad \text{(LXIII)}$$

Barrel.— If d be the inside diameter of the end of a barrel, c the inside diameter at the middle, and l the length (or height) of the barrel, then the prismatoidal formula (XLIV) gives as the volume v

$$v=\frac{\pi}{6}l\left(\frac{d^2}{2}+c^2\right), \quad \frac{\pi}{6}=.5236. \quad \text{(LXIV)}$$

The following is said to be a better approximation:

$$v=\frac{\pi}{9}l\left(d^2+\frac{5}{4}c^2\right), \quad \frac{\pi}{9}=.349\ldots. \quad \text{(LXV)}$$

The volume v of the smaller portion of a partly filled barrel, that is, of the contents if the barrel is less than half full and of the empty portion if it is more than half full, is

$$v=.000472h(d^2+a^2+4b^2), \quad \text{(LXVI)}$$

where h is the distance of the surface of the contents from the nearest end, a is the diameter at the surface of the contents, and b is the diameter half-way between the surface and the nearest end.

WILLIAM FINDLAY.

MENTAL DEFECTIVES. See CHILDREN, DEFECTIVE; EDUCATION OF FEEBLE-MINDED OR MENTAL DEFECTIVES.

MENTAL DISEASES. Mental diseases may be of a great variety of types, of great variation in degree of intensity, ranging from harmless, senseless, such as, for instance, the celebrated saying of the Quaker to his wife, «All the world is queer save Me and Thee, and methinks at times Thee is also queer,» to the most destructive and violent of afflictions such as in mania, the epileptic furor, or the ecstasies of fanatical fervor. To describe them all would fill this volume.

Psychiatry is that branch of medical science that would study, organize that knowledge, and strive to modify, heal or stop mental disorders. It is a very old, possibly the oldest of the arts if not of the sciences, since distorted efforts at trying to modify nature were among the earliest functions of the primitive medicine man, the king or the priest, often combined in early history. Man and his Id have always worked on the pleasure principle. Pleasure is good, pain is bad. Dis-ease is some form of pain, hence bad, originally a foreign spirit to be exorcised, as by the primitive medicine man; today, some distortion of reality by a demanding Id impulse. The pathway travelled from ancient times to the present is worn, and beset with many conflicting ideas about mental disorders. Naturally this would be so when the complexities of mental functioning are taken under consideration. To one who would glimpse this history, the first warning is to be made aware of the tyranny of words. In logical science, it is the disease of nominalism. The Id, roughly analogous to the gasolene of a motor car, is the source of the main chief drives, for good or evil. This power needs to be regulated. Inhibited or repressed are words used

to designate this process, and the «Ego» the reasoning process having this variable function in hand. This is not the «Ego» or «Me» of the layman. Also another important check on the Id comes from an old and yet new source, the Super-ego, ancestrally learned and familiarly relearned principles. Everything we do or think is a balanced activity of these three sets of influences. When the «Id» will not give way to be controlled by the Ego and Super-ego, and gains its partial satisfaction through a *distortion of reality,* this, in the Freudian formulation, is a mental disease, a psychosis. Thus as an illustration, the psychosis known as «melancholia,» in which depression of mood, slowness of movement and ideas of guilt are the prominent signs. Psychoanalytic study has shown that the Id impulse that, for a variety of reasons, may be set in action, is one of hostility, or aggression, which could lead to murder (criminosis), but the Ego and Super-ego get to work, handling the impulse by a process of repressive incorporation. The love hate object, is incorporated, swallowed, *introjected,* as the breast was originally swallowed in nursing, and thus devoured. The Super-ego creates the sense of guilt. The Ego has distorted the real object of the ambivalent love and hate, the mother, after converting her into a holy image, even an hallucinatory angel with wings, etc. This is a complicated process. Simpler ones will be pointed out later.

That tendency to make a «word» stand for a «meaning»: the most significant of this type of difficulty is the word «insanity,» for instance, which has falsely come to be thought of as a synonym of mental disease, because of a 2000 year old faulty connotation. It started, Pliny the elder says, somewhere, with the property and imperial minded Roman lawyers. In those days they had the same difficulties with wills, contracts, murders, etc., etc., as we have today. Problems of responsibility, capacity to remember, etc., were then as now, and the doctors had to be consulted. These doctors were nearly always Greek, or Hippocratic in training. They followed the rules of analysis then as today. The patient was an individual, and he was so and so, or such and such, to which the terms anoia, paranoia, etc., were given. This was too much for the Roman lawyers. Away with your Greek subtleties! We will lump all these diseases and call them *insanities.* Thus today think most of the lawyers, and the courts of law and the whole machinery of medical jurisprudence. «Insanity,» psychiatry claims, is not a medical conception. It is a legal status made by a court of law. A person never is, but by reason of mental disease or defect «should be declared» to have a certain status before the law. Irresponsible for a homicide or theft, incompetent to know the extent of his property and the legal objects of his bounty, or whatever the specific question may be, instead of again using an anachronistic word, calling all of these various grades of social maladaptation, again by one word, insanity. This situation is one of the many that would support Charles Dickens when one of his characters states, «The law is an ass.»

In psychiatry as everywhere else in the growth, correlation and codification of knowledge, there is much confusion, overlapping, conflict and lag, but the main pathways through the jungle can be discerned and reduced to description.

As in all things of the spirit, the Greeks seemed to have been the harbingers of advance. Psychiatry began to be studied and understood by them. Some of psychiatry's most recent conceptions had definite and clear expression among the Greeks of the age of Pericles, even if the words used are not those of today. The poets and dramatists of Greece were the original psychiatrists, or as Whitehead puts it, «the ancient Greek tragedians, Aeschylus, Sophocles and Euripides, were the Pilgrim Fathers of the modern scientific imagination.» They used the word «Fate» where today science tries to use the word «law.» They stressed the innermost motives of many psychoses, and Freud's Oedipus complex conception had its first succinct expression in the dramas concerning the «House of Atreus.»

The Greeks, however, were not systematizers in those early days, but they distinguished and described certain forms of mental disease, which descriptions hold today in part, their ideas of causation apart. In rough terms anything then was «bile,» just as thirty years ago, everything was bacteria and toxins, and today it threatens to be endocrines and allergies. Every new discovery is the rallying point of a horde of devotees who spin off into a vortex of enthusiasm, rich in the gathering of new observations, and ultimately all fall back into the arms of the old Greek conceptions, the oneness of the body, and its wisdom.

Speaking very broadly, man's behavior, both within the organs of his body (organ behavior) and within his social setting (every day behavior) is a resultant of contradictory or limiting dynamic impulses. Man lives in a world of forces, he himself is a part of that world and only superficially separated from it. Through eons of time and by the process roughly understood as evolution he has come to be able to use for his own advantage and that of his neighbor, some of these forces that move him. Briefly they live within him and are active about him. Through evolution, *patterns of behavior of survival value* have been formed. Trial and error, have moulded these patterns, the good ones, so-called, survive, the bad ones are dropped but not all at once, nor in as sharp a manner as the phrases indicate. There is always a load of both to be managed. Thus man comes into the world with a long history of experience and with the possibility of a host of reaction patterns. Heredity is a name given to the more constant or stable patterns, whether they be organ patterns or social patterns. Thus one may speak of a «liver» as a bit of organized experience (Maudsley), which through eons of time of trial and error has stabilized its structure, learned its job and standardized its behavior. Every organ of the body can be so viewed. One organ of the body has grown as a sort of adjustor or regulator, or correlator of all the other organs of the body. This organ is the nervous system, made up of cells like other organs of the body, differing in structure and in function. The functions are, roughly speaking, to regulate and correlate the growth processes (metabolism) of the other organs of the body, to move and remove those organs of the body which have specific sensory and motor functions, and finally

through a process of abstraction to know or feel, or intuit the meaning of the environment, internal as well as external. This last function —a symbolic one—is called mental and by a mental disease, is understood a disturbance of the *meaning* of the environment, chiefly social.

Broadly speaking then three issues may be distinguished. There are diseases, solely or pre-eminently metabolic; these are mostly dealt with in the sphere known as Internal Medicine; there are diseases of the sensori-motor apparatus, these are mostly thought of as Neurological Disorders; and there are disorders of the symbolic functioning of the body, these are the Mental Disorders. There are very few disorders of the body however in which only one of these functional systems is alone involved. Even Socrates learned from the Thracians this important principle of the oneness of the body and its disorders.

When one comes to view the functioning of the dynamic symbolic systems, that is usually called the mind (statically), one gets insight into a definition of mental disease by a consideration of the Freudian formula of the relative energy activities in the instinct part of life —life and death instincts—love and hate if one will roughly speaking (creation or destruction) which in the formula is called the «Id.» The «Id» already likened to the gasolene of an internal combustion engine, supplies or is the reservoir of the creative power, the productive energy. That mental institution which has grown up to be a tester of the reality of the external world is called the «Ego.» Scholastic psychology has called it the Reason. Its chief function as a reality tester is to permit, or allow the energy coming from the Id to get its way, but an adaptive way, a useful way. It is a repressing mechanism and acts like a brake on the Id energies. To aid it the Freudian formulation adds another control mechanism, the Super-ego, which is largely built up on parental patterns and old survival values. It has been called «Conscience» in the older static psychologies.

When there is a conflict between the Ego and the Id and the forces of the Id are repressed one speaks of a psychoneurosis. In the hysteria psychoneurosis the repressed Id energy is drained through some bodily symptom —Conversion. In the compulsion neurosis a subsitution mechanism ensues. It is like a ritual. When however the Ego has to give way to the forces of the Id—the Ego then changes the environment. This is the formula of a definite mental disease, the psychosis. Psychoneuroses and psychoses are both mental disorders, but differ as to mechanism involved. There are mild recoverable psychoses and severe chronic psychoneuroses.

Classification.—Almost every psychiatrist of repute has attempted a classification of the mental disorders. The subject is one of peculiar difficulty, owing largely to the fact that our intimate knowledge of many of these various forms is far from complete.

A scheme of classification adopted by Jelliffe and White regards the diseases of the nervous system as falling into three general classes: (1) Those of the physico-chemical systems, affecting the neurology of metabolism, and expressed in visceral neuropathology and diseases of the glands with internal secretions; (2) those of the sensory-motor systems, including affections of the cranial nerves, the peripheral neurons, the spinal cord, medulla, cerebrum and cerebellum and the meninges, with syphilis of the nervous system, and (3) those of the psychical or symbolic systems (neuroses, psychoneuroses and psychoses). The last contains the manic-depressive group, the paranoia group, epilepsy, dementia precox, exhaustion and toxic psychoses and those associated with irreversible organic diseases, with senility, and finally idiocy, imbecility and feeble-mindedness. This last group are the mental diseases.

A most detailed elaboration of these appears as the 1935 classification of the American Psychiatric Association.

The methods of examination of the nervous system include a questionnaire covering the family history of the patient and his illnesses, and an elaborate physical examination of the vegetative nervous system, of the sensory and motor systems, followed by a thorough mental examination which in many respects is somewhat similar to the questions of the «intelligence tests» and qualification tests of the army. The psychiatrist comes in contact with a great many diseases whose mental element is very small, no greater in fact than that of the so-called physical diseases. The disorders in the physico-chemical systems produce diseases with mental aspects, but aspects no more mental than those of the diseases affecting the organs, muscles, glands, etc., to which those nerves go. It is only when we come to what are called the neuroses that we find mental behavior alone or predominantly disordered. These affections were called neuroses or «nerve troubles» on the supposition once accepted that the mental behavior was caused exclusively by some peculiarity, whether called abnormality or merely variation, in the structure of the nerve cells themselves. At the present time, however, scientific thought tends toward the conception that mental disease is determined by the loss of balance between the organism and its physical and psychical environment.

Thus there are nervous systems congenitally so weak that they are practically disintegrated by the conflict of the individual and society, a conflict which is, as often as not, absolutely unconscious, and which occurs in the simplest and least complicated social environment. In such natures mental disease at once appears because of the individual's inability to adapt himself to the rudimentary requirements imposed upon him from without. On the other hand, there are neural constitutions so strong or elastic that they are equal to a very severe strain of adaptation even to extraordinarily complicated environment. Such constitutions will naturally adapt themselves, retaining their own personal equilibrium and health, to conditions which would completely upset a weaker (that is, less adaptable) constitution. It may be here noted that the European wars brought out many such diversities of neural constitution in those subject to «shell shock» or other war psychoses, together with improved methods of testing for congenital neural weakness. These tests have resulted in putting in positions of less nervous strain those who are unable to stand the greater. A similar allotment of individuals to the various tasks of life would naturally result in less nervous disease. For it

is evident, when both factors are taken into consideration, the constitutional factor and that supplied by the environment, that mental disease is largely a matter of proportion between the nervous system and the load which is placed upon it. For example, a person who is not obliged to struggle for existence may never develop a mental disease which he would have developed, had he been subjected to the stress of adverse circumstances, while, on the other hand, his affluence may make him introversional, and, after the age of puberty, cause him rapidly to run counter to the demands of a true social existence.

The rôle of the unconscious in the etiology of mental diseases is a dominant one, and the comparative indefiniteness of the delimitations of the various types of mental disorders is due to the newness of any scientific knowledge concerning the unconscious portion of mental functioning. The neurologist should have, though unfortunately comparatively few do, as thorough a knowledge of the unconscious mental mechanisms as can be acquired, in addition to the medical specialist's knowledge of anatomy, physiology and histology.

But the conflict, conscious or unconscious, which occurs at the psychical or symbolic level of the Ego is manifested in predominantly mental modes in the so-called neuroses, psychoneuroses and psychoses. Of the psychoneuroses the commonest are *hysteria, compulsion neurosis* and *anxiety hysteria.* Of the actual neuroses there are *anxiety neurosis* and *neurasthenia,* while special cases present mixtures of these neuroses. As a mental disease, and not as popularly used to denote an uncontrolled emotional state, *hysteria* is now regarded as a partial dissociation of the personality, in which certain mental elements, namely, emotions and ideas, have been rejected from consciousness into the unconscious where they have an existence which is at least partly independent—an existence which is of vital importance to the welfare of the individual because it is an existence in which the split-off ideas and emotions have a growth or development of their own. This development is different in hysteria and in compulsion neurosis. In hysteria the mental elements, which are repressed from consciousness into the unconscious, direct or control a portion of the libido in such a way that its force has an incidence not upon the world of external reality, as is the case with the average person, but in the shape of work done in some shape or other. On the contrary the incidence of the libido falls upon the physiological functions themselves or upon certain of them through a variety of symbolic selection. This process, which is known as hysterical *conversion,* produces very many symptoms, mostly of a so-called bodily nature. There results from this a large number of disorders which the general practitioner is prone to regard as having only a physical cause, and he prescribes drugs, which rarely have the desired effect. Possibly the commonest form of this is the hysterical headache, which is rarely recognized of psychogenic origin, although it is so completely analogous to the «nine o'clock illness» of school children, who use this gentle form of unconscious malingering as a means for escaping their responsibilities. «An adult ought to make a call upon a recently bereaved friend.» This is recognized as a distinct obligation but the patient's infantile necessity of escaping reality and seeking pleasure makes the duty seem a very onerous affair. Thus arises a conflict between duty, born of conscious appreciation of the social obligation, and desire, born of the childish inability to make the necessary sacrifice of personal comfort. As a result the patient develops a headache and so, being ill, does not have to go. While the mechanism in other hysteric conversions is more complicated, it is no less clearly proved, so that the number of what are ordinarily taken as symptoms having a merely somatic cause, and which are through analysis seen to be merely hysterical conversions, is augmented daily. Disturbances of sensibility, such as hemianæsthesia or insensibility to touch and pain on one side of the body only, disturbances of motility such as choreiform movements, tics and certain occupation spasms, disturbances of speech, sometimes including stuttering, visceral disturbances showing vomiting and diarrhœa, vaso-motor disturbances and emotional disturbances, particularly in cases of great exaltation or depression, are all likely to be caused by the hysterical dissociation before mentioned, in which some mental factor is repressed and therefore driven outside the pale of conscious control.

In *compulsion neurosis* there is no conversion, which implies a shifting of the *libido,* i.e. energy from the external world, which is its natural goal, to the physiological processes of the individual; but there is another kind of shift, namely, from the external world to the mental states themselves. In this condition the numerous physical symptoms mentioned as being found in hysteria are generally absent, but their place is taken by variation from the conventional modes of thinking, Such variations to be sure are far from unpleasant, if they do not become too great, for they add much of piquancy and interest to a person's character. But when the departure from the conventional is excessive and both compulsive and unaccountable, the condition merits the term neurosis and requires treatment from the analyst. There are compulsive thoughts, compulsive doubts, fears, acts, rituals of dressing and undressing or eating for which this kind of neurotic can give no reason. He generally does not attempt to rationalize them but admits he does not know why he always has to act or think in his own peculiar way. Analysis has convinced Freud that «obsessions are always transformed *reproaches,* returning from repression, which always refer to a pleasurably accomplished sexual action of childhood» and that «the compulsive ways of thinking and acting are only substitutes for the reproaches which are symbolical distortions formed in order to prevent a recognition on the part of the patient of the real meaning, so as to keep from his consciousness a realization of the circumstances of his guilty conduct.»

Paranoia is a group of mental diseases containing the paranoia as defined by Kraepelin, and various mixed aberrant forms, some of which are called paraphrenias. In general it is a disease in which there are delusions of persecution that have been pretty well systematized. The disease progresses usually through four rather well-defined stages. In the first the patient is unduly concerned about his health,

and particularly about what goes on around him in relation to himself. That is, he considers more things are said and done with reference to himself than does the ordinary person, and he begins to reason it all out that there must be some agreement in the actions of persons or things around him, usually for his discomfiture or ruin. Hallucinations of hearing are common. The result of his thinking himself to be the victim of persecution is that he sometimes becomes very dangerous, and attacks the persons whom he regards as his persecutors. In advanced cases the system of ideas worked out in justification of the suspicions of persecution or conspiracy is very elaborate, and frequently includes falsifications of early memories, which contribute the grain of truth in some of the projected reproaches. Another classification of the paranoia group of mental diseases is that into two divisions, the *original* and the *acquired*, the first being the inevitable development of a character which was of such a constitution as to develop into exactly this form of mental disease, in spite of an environment even partly favorable to a wholesome life, and the second, the effect of an untoward environment upon a neutral constitution which might in more favorable circumstances have escaped this fate. According as hallucinations are or are not present, these groups are further divided respectively into *paranoia hallucinatoria* and *paranoia combinatoria*. Furthermore the individual cases are described as persecutory, expansive, querulous, litigious, inventive, reformatory, religious and erotic, according to the forms which the more prominent mental symptoms show. A third division of the paranoia group is into delusions of interpretation and delusions of revindication. In the first the erratic element is in the interpretation of the factors of the environment of the patient, who remains otherwise quite clear minded, and in the second there is a tendency toward the formation of a fixed idea, either egocentric or altruistic. As paranoia was considered an incurable, progressive and chronic disease, those cases which through analysis have been shown to have at the basis of them an idea that could be traced out and corrected, and which therefore have been called acute paranoias, necessitated a further reconstruction of the concepts underlying the classification. The result of this is that the content of the mental states in this form of disease is not now considered so indicative as the mental mechanisms involved. This implies again that it is not so much the delusion, or the suspicion itself, or any other of the symptoms, which used to be considered characteristic of the disease, but it is the inability on the part of the patient to adapt his Ego to those ideas which form the so-called content of the paranoid state. The delusion, for example, is found to have been made by the patient for the purpose of making a certain emotion tolerable which he could not get rid of. The removal of the delusion would not in such a case help, for another would have to be supplied in its place, to handle the original emotion, which would itself remain. The emotion or a lack of control over the emotions is thus seen to be the most fundamental cause of the disease. The explanation of paranoia consists, therefore, in the emotional lack of control, which fixes upon certain ideas and is unable to change them, and furthermore in an exaggeration of the mechanism of projection. (See MECHANISMS, MENTAL). Finally Sigmund Freud states that paranoia is dependent upon a homosexual fixation in the psychosexual development of the individual. Treatment of paranoia has been more earnest and determined of late, as more and more cases have been handled with greater success, but it is to be remembered that the curable cases are now by many regarded as only paranoid forms of other mental diseases, and that the true paranoiac is known as paranoiac virtually only by the failure of all efforts to improve him. Psychoanalysis is the only means by which any satisfactory knowledge can be gained of the unconscious mechanisms dominating any given case, and only by a thorough study can it positively be determined how much or how little can be accomplished in the way of therapeusis. Shock therapy is an aid.

Epilepsy and various convulsive types of reaction including the classical epilepsy, some attenuated forms such as affect epilepsies, and those of gross brain disease, constitute a class of mental disease in which there are well-known physiological and anatomical changes in the brain itself. The disease is apparently hereditary, in the sense that in the history of all epileptics there is usually to be found some taint in the family or in collateral branches. The epileptic convulsion of the classical type is a spasm with unconsciousness, preceded by a warning called the aura, and followed by a gradual wakening or a deep sleep. The variations are exceedingly numerous. Modern investigation has shown that there is some association between the epileptic fit and the gratification of unconscious wishes. Epileptics are likely to be of a low order of intelligence and their reactions to be analogous to those of children or infants. Some cases indeed do turn out later to be imbeciles. Treatment is not generally considered to be of avail, except possibly in psychogenic cases, where analysis can sometimes straighten out the complexes of the patient. The best care is secured in the colony plan where training in healthful outdoor occupation is possible.

The *Dementia Precox* (Schizophrenia) group of mental diseases contains the so-called dementia simplex, hebephrenia, catatonia, some paranoid forms and certain mixed or atypical states. The mental symptoms of the dementia precox group include an emotional dullness which is thought to be due to the fact that in this disease the patient shuts himself into his own thoughts and is therefore less moved by external occurrences than are ordinary persons. That is, his thoughts lose their reference to external reality and the result in the worst cases is that nothing in external reality can move or arouse the confirmed dementia precox patient. Another feature which is an outcome of this segregation from external interests is his so-called negativism, which is shown in his either refusing entirely to do what he is told or doing it as negatively as possible. Thus, if he is told to hold out his hand, he puts it behind his back; if told to stick out his tongue he shuts his mouth tight. This segregation of the behavior from all relations with external reality (and in the last analysis reality amounts to little more than the relations of the indi-

vidual with other persons), is a splitting of the personality, which is the reason for the alternate name of dementia precox: schizophrenia or «split mind.» The detailed features of this separation of the behavior from all that in the average man is in close connection with his behavior are as numerous as all the possible types of relation of the individual with his environment. Some of these are suggestibility, failure of voluntary attention, disturbance of orientation, disorders of memory. The delusions have been shown in many cases to be symbolizations of the conflict going on in the unconscious. The fact that the conflict is unconscious accounts for the difficulty of getting at it and of re-establishing satisfactory relations with the patient. Other symptoms are bodily such as the mannerisms, stereotyped modes of action, unusual words or expressions so frequent in dementia precox, and the rigidity and stupor which characterize some of the patients.

Whatever reactions to the environment remain in the patient are marked by an archaic or primeval character, such that in the evolution of human behavior the highest, most complicated and latest acquired types are those first to be lost. In the disease the individual reverts or regresses to a form of behavior which may possibly be supposed to have been valid and current in prehistoric ages. As behavior may be regarded as built outward from a central core, this form of psychosis is what is known as an introversional one, that is, one in which the libido introverts or regresses to a more fundamental and therefore more archaic form of gratification. There are other physical concomitants sometimes noticed, such as an unusually small heart or a tendency to pulmonary tuberculosis. The onset of the disease is either gradual or sudden. If gradual it may be mistaken at the beginning for other types of mental disease, such as the manic-depressive, hysteria, compulsion neurosis, etc. It is in this disease more difficult than in most others to make any satisfactory statement as to whether it has a physical or a mental origin. As the bodily changes so far discovered have been so few and their bearing so uncertain, it is more advantageous at the present time to explain the disorder on a purely psychological basis. The patient is faced with a situation in which the balance between environment and congenital ability to adapt to it is provisionally lost, whether because of the disproportionate burden placed upon him by his environment, or because of his innate weakness rendering him unable to support the average load. In this connection it is to be remembered that many ordinary persons declare their burden is too heavy for them to bear, and that few ever know their extreme abilities; consequently the loss of balance may have a purely psychical cause lying within the unconscious desire of the particular person. When a person says that something will drive him crazy, he is unwittingly expressing an unconscious desire, not to become ill mentally, but to receive the care and symbolic homage which is given to the mentally ill. The severity of the mental symptoms may be regarded as a measure of how far the unfavorableness of the environment has driven back the individual patient from reality. There are cases of moderate confusion which appear in almost all respects perfectly natural persons, and only later develop a disorder great enough to dissociate them from their fellows; while in the so-called catatonic cases the inability is generally complete. The cases which have subsequently become well have gradually made an adjustment to reality in some form, either indirectly through the formation of delusions, or directly by a final domination of the reality motive. Cases that do not get well tend to sink to lower levels till they reach one on which they can succeed in maintaining themselves with comparative steadiness. This is notably the case in institutions, while in the world of life such persons join the ranks of tramps, prostitutes and petty criminals, thus finding their appropriate level.

The treatment of the bodily signs as such is usually of no service; the treatment of the mental condition must take into consideration the involvement of the higher or psychological levels of the personality and give as much analysis as possible, in order to reconstruct the social relations if that can in any way be done. Prevention of this disease is one of the most important ends that could be achieved by civilization, and is primarily attained through eugenic methods, lacking which the only means at present known lie in the correction of all irregularities of character as early as they may be observed in childhood and an absolutely frank and scientific handling of the question of sexuality, the source of much that is anomalous in human behavior.

A division of infection and exhaustion psychoses comprises those resultant upon fever, exhaustion or collapse such as from typhoid fever. While all these diseases have mental aspects, the treatment of them is so essentially in accordance with the disease of which they are themselves virtually only the symptoms that they need not be described here in detail. There is a special form of mental reaction following the over-indulgence in alcohol, in opium, cocaine, bromides, carbon monoxide, lead, mercury or from uremia, diabetes mellius, pellagra and certain gastro-intestinal diseases. In none of the mental diseases is the matter of individual psychology more important than in alcoholism, as the reasons for drinking which are assigned by people in general are mostly rationalizations. (See MECHANISMS, MENTAL). The real cause why people drink to an extent which harms them is that their neural constitution craves the gratification which they get from this source alone. The very fact that a man or woman cannot stop drinking therefore stamps them at once as having a weakness in their mental organizations. The alcoholic takes his peculiar way in creating an artificial balance, so to speak, in order to make up for the loss of balance between his mental organizations and the demands made upon it by his environment. It is his way of taking the cash and letting the credit go. Alcohol is the quickest path for some persons to shut out the world of reality, which has been found too arduous, and to open up the world of fantasy, the fact that the individual is unable to face reality being the really important point. Accordingly it is not surprising to find that ordinarily the alcoholic is in other respects, aside from his alcoholism, an example of general inefficiency. His unconscious appreciation of his essential inferiority is partly what leads him to flee from the world

of reality to the world of intoxication fantasy. That alcoholism is an indication of a deep psychological weakness, too, is to be inferred from the high mortality in pneumonia and other diseases among alcoholics. There is the wish to die.

The same remarks could be made about the mental aspects of indulgence in opium, morphine, cocaine and other poisonings. The amount that any given individual can stand depends, as is well known, on the mental organization. The more he can stand, the stronger the mentality; but from another point of view, the greater need he has for some drug to change, through its effect upon himself, the nature of his relations with the external world, the weaker he is as a mechanism and the less suited he is for the field of activity in which he finds himself. In all of these drug indulgences the treatment of the patient by means of other drugs is merely palliative and does not go to the root of the matter. The only hope of doing this is through psychoanalysis, after the acute disturbance has ceased. There are psychoses, too, associated with organic diseases such as apoplexy, chorea, paralysis, multiple sclerosis, polyneuritis and heart disease; also with presenile, senile and arteriosclerotic conditions.

Finally feeble-mindedness, idiocy, imbecility, regarded as defects in personal endowment or development, have the mental aspect that they cannot live in society acceptably to the degree of being either self-supporting, or of supporting anyone else. The economic importance of these defective classes is being recognized and the more as psychological methods have been devised for grading all individuals into the classes which show characteristic differences parallel with the differences between children of ages between 1 and 14 years of age. Very extensive researches by Binet, Simon, Goddard and Terman have shown that the general intelligence grows steadily up to age 14, while above that age there are roughly three groups, the low, average and high adult intelligence. What is meant by feeble-mindedness, imbecility and idiocy can be given a very exact form in a table like the following:

Mental age	Capabilities	Class
Under 1 year.	Helpless.....	Low class idiot
1 year.....	Feeds self. Eats everything.....	Middle class idiot
2 years....	Eats discriminatingly....	High class idiot
3 years....	No work. Plays little...	Low class imbecile
4 years....	Tries to help.....	Low class imbecile
5 years....	Only simplest tasks.....	Middle class imbecile
6 years....	Tasks of short duration. Washes dishes.....	Middle class imbecile.
7 years....	Little errands in house. Dusts.....	High class imbecile
8 years....	Errands, light work; makes beds.....	Low class moron
9 years....	Heavier work. Scrubs, mends, lays bricks, cares for room.....	Low class moron
10 years....	Good institution helpers. Routine work.....	Middle class moron
11 years....	Fairly complicated work with only occasional oversight.....	Middle class moron
12 years....	Uses machinery. Cares for animals. No supervision. Cannot plan...	High class moron

The advantages of these so-called intelligence tests, so clearly shown in the organization of the national army, are of further advantage in finding out whether a mental defect is inherited or acquired, because in the inherited mental defects a termination of the individual's ability to go through the tests is quite even. He can do all of the tests of ages one to seven, for example, but cannot do any of those above that age. On the other hand the case is not so clean cut with acquired defects, the individual being able to do some but not all of those tests several years above his mental age and not all of them below it.

In conclusion it should be emphasized that the mind and the body are one unity and whatever affects the one is not without effect upon the other, that it is almost if not quite impossible to draw the line between mental and bodily disorders, and that the ultimate truth will be found in the statement that mind is but the function of body and body but the perceptible expression of mind. Therefore few diseases can be regarded as exclusively mental and but few as exclusively physical. Consult Jelliffe and White, 'Diseases of the Nervous System' (6th ed. 1935); Bleuler, 'Psychiatry' (trans. by Brill); Henderson and Gillespie, 'Psychiatry' (New York 1936); Menninger, K. A., 'The Human Mind' (1936). SMITH ELY JELLIFFE, M.D.

MENTAL HYGIENE. Hygiene has usually been conceived of as a system of measures for the creation of conditions *without* for the maintenance of the *bodily health.* Mental hygiene is an effort to create favorable conditions *within* which will make for *mental health.* Whereas hygiene heretofore has dealt with external conditions which are favorable to health, such as fresh air, sunshine, pure food, exercise, etc., mental hygiene deals with the principles of right living as they apply to the regulation of our thoughts, our feelings, our activities. In its practical applications mental hygiene attempts to deal with the problem presented by the tremendous demands of our fundamental instincts for adequate expression. It sees in human failures inability to adequately harness these instincts, while in success it sees them adequately expressed in activities that are at once creative and socially acceptable and valuable. The principles of mental hygiene receive their formulation as a result of an understanding of the development of the human mind from earliest infancy to adulthood expressed in terms of a constant interplay and compromise between instinctive desires and social repressions. These principles will receive their application along two main lines of endeavor. One by applying them to the scheme of education, modifying it and minimizing the severity of these conflicts, and secondly, in individual instances by an examination of the particular situations under which difficulties have produced disturbing symptoms in the individual.

As soon as the difficulties of the individual are seen as evidences of his endeavor to make his particular instinct-constellation fit in with the social requirements, it is seen that a vast amount of convention, particularly the criminal law, is the reaction of society against instinctive manifestions by an effort at forcible repression, and just as education would not be complete if it stopped wholly at efforts of repression just so mental hygiene points out that society's methods of dealing with its delinquents are not complete when measures of repression, censure and condemnation alone are used. As

in dealing with the child it is necessary to search for and help to develop all the positive characters of value, so in dealing with the delinquent it should be society's effort to search for and develop to their fullest extent all those strivings for better things which no one is without.

This new point of view is applicable to every relation which involves the individual and society, and its ideal must be to bring about a state of understanding rather than a blind clashing of instincts between these two. When this is done individual instinctive indulgence, instead of being met by blind social condemnation, will be met by an intelligent vision which sees the indulgence as a relatively infantile, undeveloped type of reaction and which sets about to bring to pass a different reaction formula by methods of repression where necessary and to the extent necessary carefully checked by adequate controls but which does not neglect those educational procedures without which no repression is safe.

The practical application of the principles of mental hygiene must come about as a result of a more complete understanding of the developmental stages of the human individual and this means specifically a more complete understanding of the development of the child. This is the "century of the child" and in many ways the advances that have been made in child study point the way toward an adequate hygiene of mind. This is so because in all of the defective and delinquent conditions, as we find them either in children or adults, we see evidences of defective psychological development either gross or in detail. In other words, the adult delinquent, or the mentally ill adult, presents distinct evidences of having been arrested at some point in his psychological development, so that in that portion of his behavior which is circumscribed by this limitation there are the outward appearances of infantilism or childishness. The moods, the grouches, the irritabilities, the petty dishonesties, lying and pilfering, the subtle cruelties and deceptions, selfishness, over-conscientiousness, prudery, emotionalism and a thousand other traits of character are all the better understood when they are seen to be childish types of reaction, and are almost immediately appreciated as such as soon as the analogy is suggested.

The immediate problem of mental hygiene as addressed to such character traits as have been enumerated above is to approach their study in the individual case with a view to unfolding the causative factors which have, within these certain areas of conduct, prevented the individual from progressing along the usual lines of development and having succeeded in this endeavor, helping the individual to find avenues of expression for this pent-up energy in more useful ways.

All these results have been made possible by a study of the development of the child and realization for the first time that the child is not simply a small adult, but has standards of conduct, points of view, attitudes of mind which it is extremely difficult, if not impossible, for the adult to feel himself into. An appreciation of these facts, together with an attitude toward the individual which is truly constructive, the parental attitude in the best sense, is what is needed. So that in the treatment of these sick individuals there is arising in society an attitude which is a development of the parental instinct as a result of better understanding.

The defects in the parental instinct have been that children have been considered the property of the parents, existing only for their use and satisfaction. This has been the history of the child throughout the ages. Now it must be appreciated that a greater sacrifice is demanded of the parent if the child is to grow up to successful adulthood. Only the interests of the child should be considered by the parent, and not the parent's personal desires. On the other hand the child should be weaned from considering that the parents belong to it and exist for its pleasure, otherwise a dependent attitude upon the love of the parents will persist into adult life. The basic necessity, therefore, for the healthy adult is a healthy relationship between parent and child which results finally in a normal, healthy emancipation of the latter, resulting in the greatest possible attainment of individual efficiency.

WILLIAM A. WHITE, M.D.
Late Superintendent Saint Elizabeth's Hospital, Washington, D. C., Professor of Psychiatry, George Washington and Georgetown Universities.

MENTAL PATIENTS, Family Care of. The term *family care* as usually employed denotes the maintenance and oversight of an ill or dependent person by a private family for compensation. The less pleasing term *boarding out* is sometimes used as an equivalent expression.

Family care in the United States is best known in connection with the placing of dependent children in foster families by welfare officials. Such care has met with general approval and is fast replacing asylum care, which had previously replaced almshouse care.

Three rather distinct systems of conducting the family care of mental patients have gradually come into existence. First, the *colony* system, which originated at Gheel, Belgium; second, the *dispersion* system, which is used extensively in Scotland; and third, the *annex* system which is used in the United States, Germany, and several smaller countries.

The distinguishing feature of the colony system is a small hospital or community house center which gives temporary care to the mental patients that are to be placed in families. The center also provides headquarters for physicians, nurses, and social workers who look after the patients in the center and supervise those placed out in families.

Under the so-called dispersion system, as conducted in Scotland, mental patients are placed in families by welfare officers under rules promulgated by the General Board of Control of Scotland. Such board licenses the homes that may receive patients, passes on the eligibility of patients for family care and inspects, at irregular intervals, the homes caring for patients. The patients placed out have no connection with institutions at the time of their placement. They may, however, have previously been institution patients, and if they become unsuitable for family care, they may then be committed to a hospital or asylum.

The operation of the annex system is in charge of the hospital or other institution to

which the patients have been committed. The physicians of the institution select the patients that are deemed suitable for family care. Social workers inspect the homes of families who would like to receive patients and report thereon to the superintendent.

Variations of these major types of care are in use in different countries.

Family Care in Belgium.—The beginning of family care in Belgium is a matter of tradition rather than history. According to a legendary story, Dymphna, the daughter of an Irish king, was murdered by her father at Gheel in the latter part of the 6th century. Some years later she was canonized and her tomb became the shrine of Saint Dymphna. Among the worshippers at the shrine were many sick persons who came seeking relief from their illness. The miraculous cures reported caused pilgrimages to be made to the shrine from distant places. A small hospital was built by the village church but it soon proved inadequate for its purpose. The visitors, who also overtaxed the small inns of the town, were given accommodations in homes in the vicinity of the shrine. Some of the sick people stayed several weeks or months with the families that received them.

Family care of the sick gradually became a permanent feature of the town. As mental patients stayed longer than others, family care of such cases naturally predominated. After many years, family care came under local government regulations. In 1852, the communal facilities of the town became the nucleus of a national colony for mental patients. Ten years later an infirmary was built to accommodate 60 patients. Later the institution was enlarged to care for 100. In 1937, an additional hospital for 100 patients was opened. The colony is administered by a medical director who is assisted by physicians, nurses and social workers. The work of these administrators is supervised by a high commission and a permanent local committee. The high commission consists of the governor of the province, the King's attorney, the district justice of the peace, the burgomaster of the city and the curé-dean. This commission supervises employe personnel, the medical program, budget and material equipment. The permanent committee is composed of the local burgomaster, local judge, three members designated by the Minister of Justice, and the physicians of the colony. This committee has charge of placing indigent patients in boarding homes, and of maintaining general oversight of homes and patients.

From 1930 to 1939 the patients of the colony notably increased and in the latter year approached 4,000. Approximately 500 patients are admitted and discharged from the colony each year. The families caring for colony patients number nearly 1,800. As a rule each family cares for two patients, although some families may have but a single patient whereas others may have three. The inhabitants of Gheel have accepted the care of patients as a family and community duty. Instruction to young married couples in the care of mental patients is given each winter at the colony center by the psychiatrists on the colony staff. The families thus acquire a high degree of skill in managing patients and are able to care properly for patients of all classes whether insane, epileptic, or mentally defective.

The success of the colony of Gheel has been so remarkable that other countries have been influenced to adopt a like system or another system of family care deemed better adapted to local conditions.

A second colony for family care of mental patients was established in 1884 at Lierneux, a village in southeastern Belgium. This colony, which was patterned after the Gheel colony, has not attained large size but is giving excellent care of the Walloon patients to whom it ministers. In 1936, the colony was caring for 648 patients, half of which were in the infirmary, and half in families in the village and surrounding country.

Family Care in Scotland.—In Scotland, a supervised system of family care of mental patients was authorized by an act (25 Aug. 1857) regulating the care and treatment of lunatics. From that time to 1913, there was an irregular increase in the number of boarded-out cases, the number in that year reaching 2,909. During the years of the World War of 1914–18, there was a decline in the number of mentally ill patients cared for in families, and such decline has continued at a slow rate. On the other hand, the number of mental defectives placed in families has markedly increased. On 1 Jan. 1939 the number of so-called lunatics cared for in private dwellings in Scotland was 1,087. The same date shows that the number of mental defectives cared for in families was 1,584.

Although all certified pauper patients in Scotland are under the supervision of the General Board of Control, asylum treatment is practically separate from family care. Many of the patients in family care never see an asylum, and the asylum superintendent does not know of their existence. A superintendent may recommend some of his patients for family care, but after they are placed in family homes, his authority over them ceases.

The administration of the boarding-out system was formerly vested in parish councils, of which there were 875. In 1929, a new local government act was passed. This act, 15 May 1930, transferred to county councils and to town councils of large burghs the duties formerly exercised by district boards of control and by parish councils under the Lunacy and Mental Deficiency acts. Accordingly, county councils or town councils select the guardians and homes that are to receive patients.

Standards of care and administration, and rules pertaining thereto, are established by the General Board of Control, but the placing and oversight of patients devolves on the local officials. Moreover, the inspection by local officials is supplemented by visits of deputy commissioners representing the board.

As the success of family care depends fully as much on the guardians as on the patients, the former are chosen with great care. They must be substantial, intelligent householders of good character and habits. Their family life must be wholesome, and all adult members must have a friendly attitude toward the patient when received in the home.

A guardian must have a dwelling large enough to furnish comfortable quarters for the number of patients assigned him. There must

be adequate provision for heating, ventilation and light, and the customary home comforts. In addition, the guardian must provide suitable exercise, occupation, and diversion for the patients in his care. A guardian can care for but one patient unless specially licensed by the board to receive more. The maximum number permitted to a dwelling is four; the numbers most commonly found are one and two.

The cost of caring for pauper lunatics in private dwellings during the fiscal year ended 15 May 1938, averaged 13s. 7d. per week per patient as compared with 23s. 8d. in Royal asylums, 21s. in district asylums, and 18s. 5d. in lunatic wards of poorhouses.

Family Care in France.—The outstanding achievements of the family-care colony at Gheel attracted the attention of the Council General of the Department of the Seine in France which, in 1890, was seeking ways to reduce the overcrowding in the asylums of the department. Representatives of the council in that year visited the Gheel and Lierneux colonies in Belgium and inspected the family-care system of Scotland. In the session of 1891, the council decided to establish a family-care colony for women patients above the age of 50. After careful investigation, the city of Dun-sur-Auron in the Department of Cher was chosen as the site of the new colony. The people of the town heartily welcomed the project, and on 17 Dec. 1892 the colony was opened with Dr. August Marie as director. By the end of 1893, 108 patients had been transferred from the mental hospitals of the Seine to the new colony. Each year thereafter showed an increase until in December 1903, the number of patients in the colony reached 900. Since that time there has been an irregular upward trend. On 1 Jan. 1936, the number was 1,323. In 1939, it mounted to about 1,500. As the colony became larger, it was necessary to make placements in the villages surrounding Dun. On the above date, there were 679 patients in families in Dun, 89 in the colony center, 550 in families in eight nearby towns, and five on leave. The largest number of patients in any of the villages outside of Dun was 122, at Ourouër.

The development of the colony center has kept pace with the increase of patients. At first it consisted of small quarters which housed the administrative personnel, and an infirmary (D) with eight beds. Baths for patients were installed in the municipal washhouse. In 1897, a small pharmacy was installed; in 1898, Infirmary R with 16 beds was built; in 1899, Infirmary D was enlarged to accommodate 12; and in 1900, Pavilion Henri Le Roux was begun. This building, which was opened in 1902, was designed to care for about 70 patients. It was necessary to have such a ward for patients awaiting family placement and for patients returned by families. Other additions to the center, installed at various times, included an autopsy room, a laundry, a bathhouse, and an assembly hall.

The employed personnel of the colony in the beginning consisted of the medical director, a clerk, and two nurses. These proved sufficient to handle a patient population of 213. The medical and nursing personnel in 1936 comprised a medical director, a head physician, three medical assistants, eight visitors, two inspectors, two solicitors, and 16 nurses, a total of 33. The administrative personnel comprised, in addition to the medical director, nine clerical employes, two laundry employes, two gardeners, a coachman, a cook, a porter, an electrician, and a chauffeur.

The colony at Dun was established primarily for women patients above the age of 50. The age limit was later reduced. A few men are received from the hospitals of the Seine to help in the heavier work connected with the maintenance of the colony center and the cultivation of the gardens. On 1 Jan. 1936, there were 22 men patients on the colony rolls.

The colony receives both psychotic and mentally defective patients, and apparently makes no distinction between these classes when placing patients. Of the 152 admissions of 1935, 62 were classed as mentally defective and 90 as psychotic. Nearly all groups of mental disorders were represented. Care is taken to place patients in families where they will be happy and will receive the maximum benefit from their new life.

The colony center maintains close supervision over the patients in family care. «Free life with active and continuous medical supervision» is the governing principle in the management of the colony. Patients living in families are as free as members of the family. Houses are usually locked at night, but during the day patients may stroll at will through the streets and parks of the city. They may also go shopping or visiting. Of course, they are required to be home at mealtime and bedtime.

The maintenance cost of patients at Dun, including compensation to guardians, supervision, transportation, administration, and care of patients at the colony center, was about 40 cents a day in 1935. The average daily cost of maintenance in the mental hospitals of the Seine in the same year was about $1. Moreover, the annual per capita investment charge was much greater in the latter institutions. The guardians in Dun receive about 30 cents per day for the care of each patient. That this amount is deemed sufficient is indicated by the fact that the colony has a waiting list of 200 families who are ready to care for patients.

At Ainay-le-Chateau a similar family-care colony, designed to care for men patients only, was established in 1900. The colony replaced an annex of Dun, which accommodated 30 patients at the time.

Family Care in Germany.—Family care in Germany originated and developed as an adjunct of an institution. As early as 1764, Dr. Engelken, a former army physician from Holland, placed patients from his small private hospital in Rockwinkel, near Bremen, in families in Ellen and other farming communities in the vicinity of the hospital. At first the placements were made without careful selection of patients and guardians, and the care given patients was not well supervised. Family care, so inadequately begun, has continued in that region down to the present time. In the latter half of the 19th century, 15 German institutions introduced family care. These were followed by 45 others from 1901 to 1914. From 1914 to 1936, war, inflation, poverty, and changes in government seriously interfered with the progressive development of family care. On the other hand, the lack of funds for

the building of new hospitals has necessitated home or family care for many mental patients.

One of the most successful of the early German experiments in family care was that made by Ferdinand Wahrendorff, director of a private institution for mental cases at Ilten in the province of Hanover. This highly esteemed physician instituted a well-planned system of family care in connection with his institution in 1880. Beginning with four patients in three families, the system grew rapidly, until at the death of Dr. Wahrendorff in 1898, it comprised 140 patients who were living in congenial homes in neighboring villages. So powerful was the influence of Wahrendorff and so far-reaching were the effects of his experiment that he has been named «The Father of Family Care in Germany.»

Konrad Alt, after securing reports from all the mental hospitals in Germany, reported that there were 1,200 patients in family care in that country in 1902. A later canvass showed that the number had increased to 2,400 in 1906. From that day down to 1915, there was a gradual increase of patients in family care in Germany. The number in that year reached 3,815. A decline in family-care cases, which began in 1916, reached its low point in 1924 when there were only 1,511 patients so cared for. An upward trend in family-care cases, which commenced in 1925, continued to the opening of the second European war in 1939. The latest available figures (1932) show a total of 5,063 patients in family care.

The development of family care has proceeded unevenly in the several German states. Prussia exceeds all other states in the extent of use of family care, having fully nine-tenths of the total family-care cases in Germany.

Along with the development of family care in Germany there has been evolved a system which cares for patients in their own families under the supervision and care of the physicians and nurses of a neighboring hospital.

Family Care in Switzerland.—Family care of mental patients in Switzerland was begun in 1901. The first placements of patients in families were made in the canton of Berne. The experiment proving successful, other cantons introduced family care in the following order: Vaud in 1904; Schaffhausen in 1907; Zürich in 1909; Solothurn in 1925; Aargau and Basel-Stadt in 1929; St. Gallen in 1931; and Valais in 1934. Although the other cantons do not have official systems of family care, many of their patients each year voluntarily welcome such care. Placement of patients in families in all cantons that have organized systems is governed by special regulations. In most cases the patient is first admitted to a mental hospital and is under observation and treatment for a time before his placement in a family is considered. If eventually deemed eligible for placement, a suitable home is found for him. While in such a home, he remains a patient of the hospital and can be returned to it whenever conditions render it advisable. In the canton of Zürich certain mental patients are placed directly in families by the official inspector for family care. In several cantons, colonies which serve as intermediate stations between the institutions and family care have been established. These colonies are managed by nurses or attendants in the employ of the cantonal institutions. The colonies vary in size, accommodating between 12 and 30 patients.

In the canton of Zürich a special organization known as the «Institution des Inspektorates für Familienpflege» was set up in 1909 to manage and supervise the placement of patients in families. The head of this organization is a physician on the staff of the well-known hospital, Burghölzli, at Zürich. The inspector decides what families are eligible to receive patients and what patients may be placed in families. He supervises the assignment of patients, and their transfer and return when necessary. He also has charge of the financial arrangements connected with family care. In this canton, there were 407 mental patients in family care on 1 Jan. 1939. The annual placement in families in the entire country is about 400 per year.

Family Care in Hungary.—Family care of mental patients was begun in Hungary in 1905. At that time the institutions for mental patients were greatly overcrowded, and funds were not available for the construction of additional hospitals. The first family-care colony in Hungary was modeled in accordance with the Gheel plan and was established at Dicsöszentmarton. Later, other family-care colonies were established. These were closely affiliated with institutions in accordance with the annex plan. Care of patients in families proved popular and the colonies rapidly developed. At the time of the outbreak of the World War in 1914, there were about 1,800 patients in family care. These constituted 17 per cent of the mental patients committed to public institutions. During the war the colonies rapidly declined. They further suffered by the demoralized condition of the country after the close of the war. Some of the colonies were entirely abandoned and others had but few patients. The total number of patients in family care in 1923 was reported as 114. With improved economic conditions which followed money stabilization, the family-care colonies again grew, and additional colonies were formed in connection with state institutions. By January 1930, the patients in family-care colonies had increased to 2,267, which comprised 26.4 per cent of all patients committed to mental hospitals.

Family Care in the United States.—Family care of mental patients in the United States had its beginning in Massachusetts in 1885. In that year a law was enacted authorizing the State Board of Health, Lunacy and Charity to place in suitable families insane persons of the chronic, quiet class; the rate to be paid for the patients so placed was not to exceed that paid in the state lunatic hospitals. State patients in foster families were to be visited by agents of the board once in three months, and town and city patients in such families, once in six months. Pursuant to this act, the first patients were placed in families on 10 Aug. 1885. At the end of that year, 29 patients were in family care. Thereafter, the number gradually increased and reached 256 in 1905. A noteworthy change occurred in that year due to the enactment of a state law extending authority for placement to the state hospitals. In 1915, the board discontinued its own selection and placement of patients and transferred many of its family-care patients to

state hospital supervision. In response to the new legislation the number of patients in family care rose to 403 by the end of 1905. Since then the number has varied from year to year.

Notwithstanding the successful experience of Massachusetts, other states were slow to adopt family care to supplement institutional care. In New York State, mentally defective patients were first placed in family care by Newark State School in September 1931. The patients so placed were children that were capable of attending public school. In January 1933, the same institution began the formation of a family-care colony at Walworth, N. Y. Success having attended these efforts, other state institutions became interested, and the state legislature in its 1935 sessions made provision in the appropriation bill for the allocation of a sum not to exceed $20,000 from the maintenance fund of each institution in the State Department of Mental Hygiene for the purpose of establishing a system of family care for patients. In the year that followed, over 400 patients were placed in foster families by state hospitals and schools. By 1940 the number of patients in family care reached nearly 900.

Nine other states, profiting by the pioneer work of Massachusetts and New York, have adopted family care for a portion of their mental patients. Altogether there were about 1,600 mentally ill and 900 mentally defective patients in family care in the United States in 1940. It is now generally recognized that such care is beneficial to both patients and foster families, while constituting a substantial economy for the state. In general, family care has been found to cost about one half as much as institutional care.

Advantages of Family Care.—The advantages derived from family care are fourfold: Patients placed in suitable families resume a measure of community life with a natural environment and with more freedom than could be possible in a state hospital. The families receiving patients have an outlet for their altruistic sentiments and acquire a secure economic status. The state hospital, relieved of many of its custodial cases, can devote more of its energies to the scientific treatment of acutely ill and recoverable patients. The state, conducting an extensive system of family care, is relieved of the necessity of building new hospitals and has a better opportunity to treat its mental patients in accordance with their individual needs.

HORATIO M. POLLOCK,
Former Director, Bureau of Statistics, New York State Department of Mental Hygiene.

MENTAL RETARDATES, Associations for Parents of. The organizational movement of parents with mentally retarded children to group together in associations for the purpose of being able better collectively to improve the welfare of their children began in the early 1930's. During the postwar period it expanded widely so that by 1951 there were more than 125 such groups in the United States and Canada, enrolling approximately 13,000 active members as well as several thousand others on an associate basis. Among the reasons contributing to this growth are the following: (1) evidence that institutions operating under state appropriations are limited in what they can do for the children; (2) increasing awareness that the usual public school programs are unsuited for such children; (3) more general dissemination of knowledge of advances in techniques relating to mental retardation; (4) rise of questioning and challenge of the validity of the finality implicit in the words: "Nothing can be done for your child"; (5) desire of parents to learn what more can be done for these children and to pursue projects in their behalf; (6) strengthening conviction that the responsibility is social—that, just as funds are raised and appropriated for the benefit of the physically handicapped, so also should money be provided for building a fuller life for the mentally handicapped; and (7) realization that it is not enough spiritually just to care for one's own child.

The activities of these associations cover a wide range, being influenced by needs and reflecting available facilities. Some organizations, interested in improving state institutions, seek larger appropriations so that there will be adequate staffs and equipment, at the same time augmenting current funds by donations and doing many little things that bring pleasure to the children. Others devote their efforts to providing various services for children at home or in schools, such as clinics for diagnosis, therapy, and guidance; play and therapy groups; classes for children ineligible for enrollment in public schools; social clubs; sheltered workshops; vocational training centers; contacts for placement in industry; and educational classes for parents. Funds have been created to establish permanent homes or communities, and in several states, with the sponsorship of parent associations, bills have been enacted providing local aid for educating mentally retarded children.

The associations are nonprofit and, except in a few instances, membership is open to all interested persons. Members participate in the activities and regular meetings are held, often with speakers professional in the field of mental retardation. Through discussions thus afforded, parents come to accept the underlying problems as general and of broad community interest, detached from their emotional and subjective elements. Each association plans and pursues its projects, supplementing them in many cases by issuing news bulletins and pamphlets and fostering public education.

To further the common objectives of these groups the National Association of Parents and Friends of Mentally Retarded Children was formed in September 1950. Its purposes embrace all such children of all ages wherever they may be located. It serves as a clearinghouse of information, sponsors research and the training of personnel, acts as liaison with other bodies in this field, and interprets the movement on a national level. See also MENTAL RETARDATION.

WOODHULL HAY,
Secretary, National Association of Parents and Friends of Mentally Retarded Children.

MENTAL RETARDATION is a limitation of intelligence due to lack of normal mental development rather than to mental disease or deterioration. It may be of any degree from dullness to profound idiocy. While the term covers many persons with a moderate handicap, it is most often applied to those with marked limitation of intelligence, whose mental capacity when adult will not be above that of an average child of 12. This group, also described as mentally deficient, subnormal, or feeble-minded, includes some 1 to 3 per cent of the general population. Mental deficiency is found in all classes of society and in all parts of the world. It has been known since the earliest times. Physical injury of the nervous system accounts for some cases; inherited factors, such as biochemical deficiencies, for others. Medical care consists chiefly of correcting remediable physical defects and improving general health. This does not change mental capacity but may improve the patient's ability to utilize his resources fully. Research encourages the hope that causes of retardation may be found, and some progress has been made toward prevention.

THE NATURE OF MENTAL RETARDATION

Mental deficiency or retardation must not be confused with mental illness. The mentally ill, psychotic, or insane person is one who has been normal but, due to known or unknown factors, has become mentally unbalanced. A mentally retarded individual is one in whom there is and always has been a lack of mental development.

The attitude of society toward the feebleminded has progressed through the stages of abhorrence, rejection, and custody to sympathetic care. At present the emphasis is on suitable training and community supervision. The most highly developed program provides for the diversified needs of the group: (1) custody for those whose presence in the community would be inimical to its welfare; (2) specialized care for those whose needs cannot be met in the community; and (3) training for those who may, after the training period, take their places in the community with a minimum of supervision.

Primitive Attitude.—The mentally deficient members of early society were devoid of human rights and were left to fend for themselves. The Spartans disposed of them through abandonment, but Christianity preached tolerance toward all deviates, and similar attitudes of commiseration were a part of the teachings of other religions. The first recorded attempt to care for the feebleminded was that offered by the bishop of Myra in the 4th century. That only custodial care—and not training—was offered may have been due to the fact that only the more pronounced and easily recognized cases of subnormality were identifiable.

During the Middle Ages the mentally deficient were confused with the insane, and the attitude toward them ranged from solicitation to persecution. It is likely that some care was given them in Flanders during the 13th century, but it was in France during the latter part of the 15th century and the early part of the 16th century that specialized care was organized by St. Vincent de Paul.

Scientific Approach.—The scientific care and training of the mentally deficient dates from the controversy which arose after the presentation by J. E. Marie Gaspard Itard (1774–1838) of the "Savage of Aveyron" before the Academy of Sciences in Paris in 1800. This 12-year-old boy, perhaps abandoned by his parents or lost in the woods at an early age, was the object of considerable scientific speculation as to the cause of his subnormal intelligence. Itard contended that he was untaught, and because of this was an idiot. But Philippe Pinel (1745–1826) held to the point of view that idiocy was congenital. Itard sought to substantiate his point of view and began a program of training. Although the boy was able to learn to some degree, Itard was finally forced to abandon the project of making him normal.

The clinical teaching program developed by Itard had in it many fine suggestions, and Itard's pupil, Édouard Seguin (1812–1880), devoted his life to the education of the feeble-minded. His system of sensory-motor training is described in detail in many of his writings. He came to America in 1850 and was an important influence in the establishment of the country's first institutions for the mentally deficient.

Early research laboratories, such as those established at Vineland, N. J., in 1906, and at Faribault, Minn., in 1910, under the direction of Henry H. Goddard and Fred Kuhlmann, respectively, contributed greatly to the understanding of the problem and to the development of training programs. The pioneer work of E. R. Johnstone and Joseph Beyers with the Committee on Provision, the publication of Goddard's *The Kallikak Family* (1912), and the introduction at Vineland, N. J., in 1909, of the original Binet-Simon tests for the measurement of intelligence are prominent milestones.

Understanding Mental Deficiency.—Specialists in a number of fields have made important contributions to the understanding of this group. The pediatrician, endocrinologist, pathologist, anthropologist, roentgenologist, psychiatrist, sociologist, educator, psychologist and others—each has made a significant contribution.

It early became apparent that mental deficiency could not be "cured" in the sense that a disease can be cured. Medical science is continuing to study the condition and some day a cure may be found, but at the present time the outlook for an early remedy is not hopeful.

The educator has discovered that the subnormal child can be trained within the limits of his ability, and many significant and highly worthwhile training programs have been developed. The sociologist has found that many can be helped to adjust to community life. The psychologist has established that he can be studied objectively, and his findings have been of considerable value to all other specialists concerned with the problems of mental deficiency.

Etiology.—The etiology or causative factors of mental deficiency are not thoroughly understood. In the individual case it is frequently extremely difficult to identify with certainty the specific cause or, perhaps, combination of causes.

During the past decade or two there has been a marked change in the overall concept of causation. Earlier research suggested that faulty heredity was a prominent factor in producing mental deficiency, but authorities rarely adhere to that point of view. While it is likely that it is still the most prominent single cause, the percentage of cases in which neuropathic ancestry is now considered to be the cause is very much lower than was previously thought to be true.

Upon thorough study of the antecedents and the growth and development of the individual child it is generally possible to determine whether the causative factors are endogenous or exogenous or, in other words, whether it is an hereditary or nonhereditary case, a primary or secondary case. Endogenous refers to gene variation, while exogenous refers to some modification of the organism.

Perhaps 50 per cent, or less, of the mentally retarded cases are endogenous in type, while the others are due to factors operating upon the organism prior to, during, or immediately following birth. Because of the difficulty of obtaining a truly representative sampling of the mentally deficient population, no estimate of the percentage of assigned causes is acceptable. Among the factors which have been found are: (1) injury *en utero*—injury during the birth process—and, infrequently, injury immediately following birth; (2) somatic variations due to little-understood changes in the functioning of the glands of internal secretion of the mother during the period of gestation; (3) diseases in early childhood accompanied by a high temperature. Other studies have pointed out that therapeutic X-ray treatment in the pelvic region of the pregnant mother —when such treatment is of a specified depth and frequency—will produce the microcephalic child; that incompatibility of the Rh factor in the blood of the mother may be found with a greater frequency in certain types of mental deficiency; and that an inordinate number of cases of mentally deficient children have a history of whooping cough at an early age.

Some of the hitherto rather well accepted causes—such as a fall in early childhood, alcoholism in the parents, fright, improper nourishment, and others of similar type—are no longer accepted with much credence.

Classification.—Mental deficiency is a symptom complex and is not a condition, the determination of which is dependent upon simple mental test results or the derivative of a mental test, the commonly used IQ (intelligence quotient). While the IQ may be helpful, as is the thermometer to a physician in diagnosing a disease, it fails when most critically needed. The skilled diagnostician relies upon a careful evaluation of such factors as birth conditions, genetic development, the results of formal and informal teaching, motor and verbal skills, and other evidences of maturation and responsiveness. In other words, the classification of mental deficiency is dependent upon exceedingly careful clinical studies.

The mentally deficient person is usually classified as to degree or grade. In the earliest days the profound mentally deficient, or feeble-minded, individual, as they were then called, was classified as the idiot; the next higher grade, as the imbecile; and the highest grade, as the feeble-minded. Goddard overcame this confusion by giving the name "moron" to the highest grade. Now there is a tendency to abandon the use, at least by some authorities, of these terms and to classify the mentally retarded into three main groups: the severely retarded (the idiot); the middle grade (imbecile); and the high grade (moron). These names are just as descriptive, and perhaps more so, than the previously used designations, and the terms severely retarded, middle grade, and high grade do not carry with them unwarranted connotations.

The Severely Retarded.—The severely retarded mentally deficient person is generally the offspring of parents of healthy stock. The number of severely retarded individuals who come from poor stock—that is, the hereditary type—is relatively small. The condition is frequently recognizable at birth or at a very early age because of the unresponsiveness of the child to his surroundings, and readily recognized physical anomalies. At maturity the severely retarded mentally deficient individual is largely incapable of self-help, has little useful speech, is incapable of independent living, and is almost entirely dependent upon others for his comfort and welfare. This type of child at maturity rarely has a mental level in excess of three years and must be provided for throughout his entire life.

The Middle Grade.—The middle-grade child is not so easily detected at birth due to the fact that his retardation is less severe and is not particularly outstanding until perhaps the age of six months or a year. While this child can learn to take care of his bodily needs, be taught to perform many simple tasks, and move about quite freely in a limited environment, he is incapable, because of mental retardation, of managing his own affairs and, hence, is quite likely to become a social problem.

The High Grade.—The high-grade mentally deficient individual—and this group constitutes by far the largest number—is frequently unrecognized. He may be considered to be slow by his parents and teachers and "dumb" by his employer. The mental level concept is not of much help in classifying this grade. Indeed, clinicians adhere to the point of view that some individuals classifiable as normal may have a mental level as low as nine years and some high-grade mentally deficient individuals may have mental levels as high as 12 to 14 years. These individuals are very susceptible to training and, providing they have been in a situation and profited by a well-planned program, they may do much useful work. Because of their mental deficiency they always need some degree of external supervision. In many instances it is necessary to have this supplied by other persons, but it is possible to have it supplied by the situations in which they have been placed. Their scholastic potentials are not high, rarely exceeding the fifth grade; but in today's world there are a great many niches into which people may fit who are not able to read and calculate at high levels.

Clinical Varieties.—There are a number of clinical varieties, some of which are readily recognizable and occur with a frequency that is sufficient to cause mention to be made of them. The most frequently observed type is the Mongoloid type, miscalled because of the child's similarity in appearance to the child of the Mongolian race. Actually this type of mental deficiency appears throughout the entire world. It is reliably estimated that they appear two to three times in every 1,000 births. They are readily distinguishable by their slanting eyes, internal epicanthi, flat head, saddle-shaped nose, elongated and transverse-fissured tongue, short, stubby fingers, full and fissured lips, and general underdevelopment or hypoplasia. At maturity their mental level is generally between four and five years and rarely exceeds seven years. They have a sunny disposition and are playful and mischievous, although they can be outstandingly stubborn. They are the "aristocrats of the mentally deficient" because

they appear in the better families. There is no substantial agreement as to the causative factors, although it is possible that this condition may be due to a polyglandular disturbance operative at a vulnerable period during fetal development. Cases are reported in the literature of more than one appearing in a single family, but such instances are rare. In spite of considerable research and experimentation it has not been found that they respond to endocrine therapy.

Less frequently found but often confused with the Mongoloid is the cretin type. Cretinism is a clinical type caused by severe thyroid imbalance which produces characteristic physiological symptoms. They are short in stature, being of the dwarf type and frequently also confused with the achondroplastic dwarf. The latter is a type of dwarfism frequently found in mental deficiency, characterized by a shortening of the long bones of the body. The torso is more or less normal, but the arms and legs are short due to a lack of a development of the chondrus, or the cartilage at the ends of the long bones.

The most frequent anomalies observed are the variations in cranial structure. Microcephaly, or small-headedness, is present in a large number of cases as is hydrocephaly, or large-headedness, due to excessive fluid in the brain cavity. Other conditions, such as dolichocephaly (long-headedness), appear frequently enough to be interesting but are not of importance.

Specialized Care and Training.—It is probably true that undue optimism will always prevail regarding the possibility of remedying mental deficiency. It is safe to say that there is no known training program or medical treatment which will so correct the defect in a mentally deficient individual that he will operate at normal levels of efficiency.

The mentally deficient require specialized care and training in the home, school, and community. The history of specialized care for the mentally deficient in the United States begins with the establishment in 1828 of the first experimental school, with an appropriation of $2,500 annually, in the Perkins Institute in Boston. This institution was incorporated in 1850 as the Massachusetts School for Idiotic and Feeble-Minded Youth, and in 1891 was renamed the Walter E. Fernald School and relocated at Waverly. New York State followed in the establishment of an institution in 1851, Ohio in 1857, Connecticut in 1858, Kentucky in 1860, and Illinois in 1865. The first private school for the care and training of the mentally deficient was established in 1852 at Media, Pa., and is now known as the Elwyn Training School and is located at Elwyn, Pa. Special classes in the public schools for the mentally retarded followed at a much later date—Providence in 1896, Chicago in 1898, New York in 1900, Philadelphia in 1901, and Los Angeles in 1902.

At the present time, although several states provide more than one residential institution for the specialized care of the mentally deficient of all ages, not all states make separate provisions for this type of individual. Special classes in the public schools are still inadequate, although more are being established from time to time. A great many of the states are recognizing the need for a differentiated attack upon the problem. This includes home training for the homebound, community classes, residential institution classes, and special classes in the public schools.

During World War II, authorities were astounded by two factors. One was the success attained by a great number of previously trained, high-grade mentally deficient boys in military service, and the degree of success attained by other mentally deficient boys and girls, young men, and young women in the war industries. Since that time there has been a marked reduction in the number of high-grade mentally deficient individuals on the waiting lists for the residential training schools. This is, no doubt, largely due to the fact that industry has found it possible to use these hands in simplified, routine operations.

While it is true that the mentally deficient contribute more than their share of social ills, it is not true to the extent once believed. They are the last to be hired and the first to be fired. They do appear more frequently on the relief rolls, and the estimated 1,500,000 in the United States cost the taxpayers a great deal of money. A careful estimate in 1947 placed this relief figure at more than $2,000,000,000.

It is not true, however, that most crimes are committed by the mentally deficient. In New Jersey a study was made in 1937 of 32,000 admissions to the penal, correctional, and juvenile training institutions extending over an 18-year period. In each of the reporting institutions well-trained psychologists saw each individual, making careful clinical studies. Out of the 32,000 admissions approximately 9 per cent were found to be mentally deficient. This is considerably lower than figures previously reported. It ranged from between 25 and 30 per cent in the juvenile delinquents to about 5 per cent in the male adult group.

A comparatively recent movement of some importance in the field has been the development of groups composed of the parents and friends of mentally retarded children who are interested in the development of additional and more adequate facilities and the better understanding of the problem. More than 100 such groups had come into being in the United States by 1951.

The single organization in the United States devoted exclusively to the problem of mental deficiency is the American Association on Mental Deficiency. This organization, founded in 1876, numbers among its membership only those who are working professionally in the field or primarily interested in mental deficiency. The association publishes the *American Journal of Mental Deficiency* and the *A.A.M.D. News*. The International Council for Exceptional Children, composed largely of educators, is interested in the retarded child as one of several groups of exceptional children. The National Association for Mental Health, primarily interested in the mentally ill, devotes some attention to mental deficiency. The National Association of Parents and Friends of the Mentally Retarded (see MENTAL RETARDATES, ASSOCIATIONS FOR PARENTS OF) is a lay organization in the field.

HOME CARE FOR THE RETARDED CHILD

Good home care is the greatest help for the retarded child. The first signs of retardation may be delayed teething, walking, and talking; lack of interest in the environment; and persistence of infantile habits. As soon as parents are aware that the child is not developing at the usual rate, advice should be sought from a specialist in this field or from a child-guidance clinic. A diagnosis indicating the degree of retardation is essential to good home management. Knowing the child's maximum possibilities, the parents should aim at helping him realize them and make the most of whatever ability he has. In daily training the chief consideration is to keep in mind the mental age of the child and manage him according to his capacity rather than according to his actual age. A subnormal child develops as other children do, but at a slower rate, so that when he reaches maturity and mental growth ceases he has not acquired average adult intelligence.

In general, all methods that benefit normal children will benefit the subnormal child if they are modified according to his ability to understand. Another general principle is that the family must be thought of as a whole, and a balanced family life maintained, without lavishing the means and time of the parents on the subnormal to the detriment of the normal. If the child requires so much attention that it is not possible to have a fairly normal home life, it may be desirable to seek institutional care.

Special measures will partly offset the special handicap. Retarded children sometimes have less than average resistance to disease, and precautions for maintaining health should be continuous. Even more important is the development of wholesome personality. In emotional stability retarded children vary as much as the normal. Some are very stable, others highly unstable. The backward child, however, is subject to emotional stresses not usually met by others. Ingenuity and patience may be needed to counter them. Security in the affection of parents, necessary for all children, is especially needed by the retarded, who suffer many rebuffs and disappointments outside the home.

Parents will do well to give constant evidence of affection and, while not indulging the child, give enough attention so that he has a feeling of personal recognition. To assure him the confidence and satisfaction that come from achievement, it is desirable to arrange chance for success through games and small tasks that are within his ability. Failures are to be avoided insofar as possible, and praise for accomplishment, however small, should be generous. The retarded child is often rejected by playmates of his own age, but he may play happily with younger children near his mental age. If he has brothers and sisters, they should be accustomed to including him in their pastimes, but not to a point where they feel him a burden or are denied the usual contacts with other children. Planned group play and simple outings are other devices for providing companionship and variety. Opportunities should be made for using all the faculties that are normal—for example, ability to sing.

When the child passes infancy, training toward self-help is begun. It is useless to attempt habit training until there is enough physiological development to enable the child to control functions, but it should begin as soon as practicable and continue until he can attend to personal needs. He can be encouraged to feed and help dress himself as soon as he has sufficient muscular coordination. Such training requires much patience, but it is very valuable to the child, besides relieving the mother of unnecessary work. Less important habits deserve consideration. Attention-getting devices, unpleasant mannerisms, or awkward gait and posture should be overcome if possible, since they mark the child as different from others. Indirect methods, such as imitation and suggestion, usually give better results than direct commands, which may make the child self-conscious.

Discipline should approximate that for normal children, but be adapted to the slower rate of learning. To be effective, discipline does not have to be severe, but it must be consistent. The subnormal child is somewhat more suggestible than the normal and has less sense of the consequences of his actions. Parents will therefore want to guard against undesirable friendships, especially as the child grows older and spends more time away from home. Reliable measures against making wrong associations are to provide companionship of the right kind, and to plan for plenty of occupation that holds the interest.

All but the most severely handicapped are capable of useful work. Mental defectives are found in a great variety of occupations but are best fitted for unskilled labor under supervision. In most cases, partial self-support is all that can be expected, but some are entirely self-supporting and even help relatives. The degree of deficiency roughly determines earning power, but other factors, such as stable personality and good work habits, influence employability. Preparation for the future begins in childhood. For those of very limited capacity, it is directed toward the maximum of self-help and usefulness, for those of higher intelligence to employability. The home program does not attempt to develop skills, but rather such habits and attitudes as courtesy, punctuality, self-confidence, feeling of responsibility, and ease in getting along with other people. Beginning with simple duties like dusting, washing vegetables, and feeding pets, the child shares in the activities of the home, at first with supervision, later without. If coordination is poor, work involving the large muscles is to be preferred. As he grows older, harder tasks, such as doing errands and making beds, are assigned. Proficiency compatible with increasing ability should be required. The child may be expected to do his share of repetitive jobs, like washing dishes, but he should not be made a household drudge. His activities should be varied and gradually broadened in scope, both inside and outside the home, and if there are any special aptitudes, they should be cultivated for possible economic value, but in any case for the satisfaction they give.

Often overlooked are the possibilities for usefulness of those too handicapped to be employable. By taking a large share of home duties, they sometimes free another member of the family for paid work, or add to the family income by acting as assistants. A measure of appreciation for such services goes far toward their contentment and happiness.

The care of a retarded child makes heavy demands on the family. Anxiety is often a chief part of the burden. Parents may find it a relief to give up specific objectives which may be unattainable, and set themselves a goal which it is possible to reach—namely, making the child as happy and as useful as his limitation permits.

(K.G.E.).

THE RETARDED PUPIL IN SCHOOL

In the schools of the United States there are many nonacademic pupils—those who, at the age of 15, will be unable to read at a sixth-grade level with interest and with profit. Such pupils should be considered in four categories: (1) the socially handicapped; (2) the socially maladjusted; (3) the clinical academic cases; and (4) the mentally deficient.

Socially Handicapped Pupils.—These are the children who are not working at normal grade level because of improper or insufficent instruction, physical defect, or poor home or neighborhood conditions. Such children are capable intellectually of doing normal or superior work. They are not doing such work because of external factors.

It is the business of the school with children in this category to see that, insofar as possible, every remediable physical or social handicap is removed or alleviated. Simultaneously the school must see, through proper guidance, that such pupils are started on an educational program that will aid them to realize their potentialities. The same program will not benefit all socially handicapped pupils. For those who have learned incorrectly a remedial program will be necessary. Those who have learned insufficiently will require a make-up program which will enable them to acquire the essential learning tools without being denied too much of the content appropriate for their social age. In both remedial and make-up programs, however, the teacher must face the fact that some content or cultural material must be eliminated in order to ensure the acquisition of the learning tools. Otherwise the pupil will be asked to do the impossible, and failure—emotional, social, physical, academic, or vocational—will result. For some socially handicapped pupils, therefore, a different developmental program must be provided. No socially handicapped pupil should be permitted to enter a remedial or make-up program unless it is reasonably certain that: (1) he will attain an actual sixth-grade proficiency by the end of his fifteenth year; or (2), being of college caliber, he will be given the sustained economic and emotional backing necessary to permit him to complete professional training. It is the business of the school to ensure sustained backing for pupils capable of utilizing it.

No one knows the incidence of the socially handicapped. Speaking from his experience in Delaware, George H. Henry wrote in *Harper's Magazine* (January 1946):

"By testing any graduating class of any high school in the country, the skeptic can see for himself what is an old story to teachers: that a third of the high school cannot read on a fifth-grade level or write a coherent paragraph reasonably free of errors. . . . The pupils who compose this lower one-third are not to be confused with the mentally backward (a far smaller group comprising only about five per cent of a school or less)."

The important thing to remember is that 90 per cent of the pupils in an average school are capable of achieving sixth-grade proficiency, not mere certification, before 16, provided that two steps are taken early enough: (1) their remediable handicaps are removed; and (2) they are placed on realistic, functioning educational programs.

Socially Maladjusted Pupils.—These children have an emotional disturbance which keeps them from doing the work of which they are capable intellectually. The disturbance may have come originally from defective environment, from defective physique, or from defective mentality. In any case the deviation has resulted in a pattern or habit of action which these individuals cannot change without help.

The school has the same responsibilities toward the socially maladjusted as toward the socially handicapped: (1) to see that handicaps are removed or minimized; and (2) to make sure that the children have worthwhile school programs. But these responsibilities will entail different timing and methods than those employed for the socially handicapped.

For the socially maladjusted, whatever the primary cause or causes of the maladjustment, the emotional disturbance must be given precedence in treatment. And the treatment of this disturbance may, and probably will, so interfere with the school program that only a different developmental program can be expected to be of benefit to them either as children or as adults. This, of course, is equally true for a second reason. Although the fact is seldom or never mentioned in popular treatises, the general intellectual level of caught delinquents is exceptionally low: the lowest 10 per cent of the population intellectually furnishes about 50 per cent of the caught delinquents.

The different developmental program must be purposeful, however. Although relationship emphases will vary, the same educational goals or objectives that apply to all other children apply to the socially maladjusted. These children have the right to leave school capable of meeting adult responsibilities through contribution at the level of their potentialities.

About 1 out of 200 children is grossly maladjusted socially, and another 5 are in need of modified treatment. Both groups need the aid of clinical experts, but provision of functional school programs will help to arrest deterioration and prevent its onset. Schools, therefore, have three responsibilities with respect to the socially maladjusted: (1) to provide sufficient expert clinical service; (2) to provide different yet purposeful developmental school programs for the two groups of grossly maladjusted; and (3) to provide realistic school programs for all children as a preventive measure.

Clinical Academic Cases.—These are children who suffer from some specific defect in learning patterns, such as seeing words in reverse. Some experts feel that the basic cause is physiological; others, that it is emotional. Whatever the cause, a child should be turned over to an academic clinician as soon as such a handicap is discovered, since it is extremely important that the wrong pattern not be deepened. As with all nonacademic pupils, however, the real cause of the defect must be ascertained. A child may be learning ineffectively because of any one of a number of reasons: (1) a lack of concepts around which to build learning; (2) emotional blocking connected with learning; (3) emotional blocking not so connected, economic and cultural causes being especially important; (4) physical defect, particularly one due to dietary, glandular, visual, or auditory causes; (5) mental defect; (6) emotional defect; (7) poor or inadequate guidance; (8) incorrect curriculum; (9) insufficient teaching; (10) poor teaching; (11) poor learning; (12) clinical academic defect.

After the cause has been ascertained, a complete program should be outlined. Such a program would provide the following: (1) prognosis; (2) plans for amelioration or sublimation

of the handicap, if possible; (3) educational plan; (4) guidance plan for child and family; (5) administrative plans to mesh subprograms and contributing personnel and to ensure that the program is carried out; (6) plans for continuous evaluation and replanning; and (7) plans for refitting the individual into society, where necessary or possible. The prognosis must be as honest as the diagnosis. A reading defect might require the services of an academic clinician, an ophthalmologist, a psychiatrist, a teacher of Braille, or a teacher of the retarded. And a reading deficiency might necessitate the initiation of a school program emphasizing long-time academic proficiency or vocational proficiency. Once started, however, an honest and intelligent program should be continued until some better program becomes apparent. Standards of promotion from one level to another within a school program, for instance, should be strict and honest. If a child cannot master a given curriculum, he should not have it. There is no education by osmosis, and there should be no planning by default.

At most there are very few true clinical academic cases. A somewhat larger number function in this way. For both groups, academic clinicians must be provided.

Mentally Deficient Pupils.—Technically, the terms "subnormal" or "inferior" are applicable to persons with below-average intelligence, and thus to about one fifth of the general population. The term "feeble-minded" has been pre-empted, though not technically, for use with individuals so defective intellectually that they will never be able to manage themselves or their affairs without a large amount of supervision. The terms "mentally deficient," "retarded," "mentally retarded," and "mentally handicapped," which can be used interchangeably, designate a smaller group than the subnormal or inferior, but, in common parlance, a larger group than the feeble-minded.

Of the one fifth of the general population that is below average in intelligence, the great majority can profit in reasonable degree from a modified regular school program, but some must be on a separate curriculum because their power of adjustment is limited. In other words, under fortunate circumstances the majority can profit from a modified regular program; under unfortunate circumstances they will need a different program. For those more grossly limited in power of adjustment—the mentally deficient—no degree of modification of the regular curriculum will provide profitable schooling. They cannot profit from a remedial or make-up program, either of which, ostensibly, would return them eventually to a regular program. The mentally deficient require a different developmental program.

Among the mentally deficient are the feeble-minded. These include the idiots, who cannot guard themselves against physical injury; the imbeciles, who are capable of a measure of self-help, ordinarily within an institution; and the low-grade morons, who often are capable of maintaining themselves in private competitive enterprise, provided they have constant supervision. Also included among the mentally deficient are many individuals who, under fortuitous circumstances, are capable of managing their affairs in adulthood without supervision, provided they have special education in childhood. These are the high-grade morons and certain borderline cases.

All inferiors are limited by constitutional defect. This limitation results, and is manifest, in a circumscribed power of adaptation to circumstances. For a given individual, inferior as well as normal and superior, happiness in a particular situation will result if the power of adaptation, internal and external, is equal to the demands of circumstance, internal and external. As a result, individuals reasonably similar in power may lead lives varying greatly in happiness or success. But no retardate is capable of getting enough from ordinary schooling to enable him to meet satisfactorily the demands of living. This is the distinguishing feature of mental deficiency.

Implications of Mental Deficiency.—Mental deficiency is actually a physical defect, but since it is not always apparent, it mistakenly is classified under a separate category. Moreover, since society for some reason has greater feelings of guilt about amentia than, for example, about dementia or blindness, persons with mental deficiency are accorded less consideration. We are sympathetic toward the blind child shown on the screen; we laugh at the comedian who imitates a moron. Many intelligent people who would be among the first to demand special service for the crippled, the blind, or the deaf would deny special service to the mentally deficient. Such people might put the idiot out of sight in an institution, but they would not give the more capable defective the special education that would enable him to keep out of an institution.

Mental deficiency has definite implications, many of which are unknown to the general public. A weak mind, for instance, is not accompanied ordinarily by a strong back. It is accompanied by a weak back, and physical defects are more than twice as frequent among the mentally deficient as among the normal. Moreover, the defective generally does not adjust easily to repetitive work, particularly on an assembly line. He works best in small groups where there is some change of operation and some personal contact with an overseer. Mental deficiency, especially among certain types, does not guarantee placidity. Not only does the lower intellectual group furnish a grossly undue proportion of caught delinquents, but the defective in the classroom is about five times as liable as the normal child to need specialized help with personal problems.

These characteristics have definite vocational implications. Only in the most unusual cases is the retardate able to maintain himself without supervision in semiskilled work; and studies, as distinguished from generalizations based on a few exceptional cases, repeatedly have shown that the retarded do best in unskilled work. Even here, however, they are competing with their more capable fellows, since about 20 per cent of the work in the United States falls at this level. Low-level jobs are terminal and not interim jobs for the mentally deficient, and yet such individuals often leave school without the necessary intensive preparation for the lowest-level jobs. By the very nature of mental deficiency, a boy so handicapped will not learn the required work casually. Thus, when the time of employment comes, the normal boy will get the job instead of the boy who is mentally deficient, not because the latter cannot do the work, but because he has not received the extra training that he needs in order to have equality of opportunity for employment. In order to obtain immediate employment and

to retain it through his employable years, the mentally deficient must be better fitted for his work, in terms of particularized training, than his competitors who have average or better than average intelligence.

The basic characteristic of mental deficiency is limitation—in adaptive power, in associative power, in learning speed—and this limitation is so great that it extends to the learning and practicing of the simple operations which the average child picks up casually. Yet, upon leaving school, mentally deficient children must meet the competition of the more capable groups. Society does not give them any special consideration with respect to employment; in fact, ordinarily it discriminates against them. Therefore, the only protection of the mentally deficient against such a laissez-faire condition is special education.

A Valid Philosophy of Special Education.—Different philosophies have been utilized as a guide in the education of the retarded. Historically speaking, each may have been necessary at some stage in the development of a valid program, but some school systems still cling to a philosophy long discarded by more progressive systems.

An early philosophy, starting about 1900, could be termed the "relief" philosophy. Under this system, special education was established to relieve normal children in the regular grades, the emphasis being placed solely on their good. As a result of this negative attitude toward the mentally retarded, anything was possible or accepted in the special class. The children and some unfortunate teacher were thrown together in an out-of-the-way classroom, and the child's time was spent in meaningless nothingness.

A more enlightened but not more productive philosophy was that of "happiness," which also flourished in the early 1900's. Under this philosophy, special education was used to remove children from extremely unhappy classroom situations and to place them with their mental equals so that they would not suffer from the unfair competition of normal children. It was believed that, by giving the mentally deficient child command of the simplest academic tools, the most rudimentary manual skills, and the most generalized attitudes, he could be made into a reasonably self-sufficient, self-supporting citizen. This type of program failed because of the urbanization of society, the rise of cultural standards and educational levels, and the mechanization of industry. Experience showed that the mastery of simple academic skills, of generalized skills, and of generalized attitudes did not produce employable or contented individuals.

In the 1920's, with newer forms of education, many educators wishfully thought that the slow child was receiving an adequate education by performing certain manual parts of an activity, such as making dioramas or doing finger painting, while the more able child prepared reports and developed dramatic presentations. Time showed that such an emasculated program for the mentally deficient left them without any real facility in meeting adult responsibilities, slowed down the rate of progress for the more able, and degenerated eventually into that true form of segregation: remaining in the same room without worthwhile participation or emotional rapport.

In the 1930's, it was discovered that the retarded had some capabilities; and so the pendulum swung from "nothing" to "everything," and the emphasis was placed on a "return-to-the-grades" or "salvage" philosophy. Academic training was stressed out of all proportion to the children's needs or abilities. The kindest thing that can be said about the program which resulted was that it did not fool its victims.

Another philosophy, not more valid, was the "handwork" philosophy. In this the child was given something "real to do." He was urged to saw and hammer, plane and chisel; and somehow, some day, it was expected that he would take his place in the ranks of honest, skilled labor.

It is now recognized that no philosophy is valid for the education of the retarded that does not guide us toward providing an education beneficial to the retarded themselves. Such a philosophy must be based on a realistic view of the strengths and weaknesses of these children as well as on the place they eventually will occupy in society. It is believed that the retarded have a potential contribution to make to the world in which they live and that it is a primary function of special education to help the retarded to realize such potentialities.

As early as 1931 the Committee on Special Classes of the White House Conference on Child Health and Problems, in *Special Education: The Handicapped and the Gifted* (see *Bibliography*), stated:

"Serious consideration must be given to the curriculum best suited to the needs of subnormal [retarded] children. The aim is to develop the child's mental capacities and the control of his emotions to the point of adequate social adjustment and the curriculum must necessarily be determined in part by adult requisities. The first point to consider is what work these subnormal [retarded] will eventually be able to do."

In *A Guide to Curriculum Adjustment for Mentally Retarded Children* (see *Bibliography*), Dr. Elise H. Martens, senior specialist in the education of exceptional children in the United States Office of Education, said:

"Education for the mentally retarded is not different in its aim from education for any group of children. This aim is to teach the individual how to live better; to teach him to use all of his capacities; to teach him to become a useful member of the social group."

Dr. Charles Scott Berry wrote in *Education of Handicapped School Children in Michigan* (see *Bibliography*):

"There has been much time, money, and effort wasted in the education of subnormal [retarded] children through the failure to recognize clearly the proper aim of education in the case of this type of child. Since about 20% of the adult population are engaged in unskilled labor the folly of attempting to prepare children of the most inferior intelligence for skilled labor or for electrical work is self-evident. The aim of the teacher, after a thorough trial in the special class has demonstrated the impossibility of the pupils ever successfully doing regular grade work, should be to prepare him to become a law-abiding, self-supporting citizen in the simplest occupations."

Thus, conscientious educators have come to see that the retarded, if they are to realize their potentialities, must be given a different developmental program rather than a remedial or impractical adaptation of a normal program. Such education must give to each child a competency in (1) the technique of self-measurement; (2)

a knowledge of suitable job families and social requirements; (3) the technique of meshing abilities with vocational and social requirements; and (4) the desire for social contribution. The whole program for the mentally retarded must be built around the achievement of vocational and social competence, for here, if anywhere, the retarded will most nearly approach normalcy. This different developmental program is called occupational education.

Essentials of an Effective Program.—Occupational education seeks to give the retarded sufficient freedom to enable him to develop his capabilities for self-support and yet sufficient protection from the rigors of competition to keep him from being too hopelessly discouraged to utilize these capabilities. It provides a series of occupational-social skills leading toward a social maturity that includes occupational adjustment as a part of total adjustment. To accomplish this aim, the complete program includes the following:

(1) *Occupational information*—giving the pupil information concerning the work available to him (considering both youngster and community): how this work is done (job analyses); and what its importance is to the world.

(2) *Vocational guidance*—guiding the pupil to measure his own abilities against the requirements of the job in which he is interested; showing other jobs in the same work area.

(3) *Vocational training*—giving the pupil training in the manual skills found in the work area (25 per cent); training in the nonmanual skills necessary in the work area (25 per cent); training in the general habits, attitudes, and skills common to all good individuality, workmanship, and citizenship (50 per cent).

(4) *Vocational placement*—providing the individual with actual job placement.

(5) *Social placement*—adjusting the adult on the job and in the freedom of his first independence for as long a period as may be necessary.

In New York City the teacher is responsible for the first three of these phases, which he provides ordinarily in the classroom, using the eight following large cores of instruction:

Core	Chronological age
The home	7–9
The neighborhood	10
The borough	11
The city	12
Study of job areas	13
Ways of choosing, getting, and holding a job	14
Ways of spending one's income wisely	15
The worker as a citizen and social being	16–17

Throughout these cores great emphasis is placed on the nonmanual or social skills. These are the skills, not of a manual or technical nature, that likewise are needed for living and working. Several recent studies show that from 60 to 80 per cent of workers lose their jobs for nonmanual reasons. Such skills include: personal health and appearance, manners, means of getting employment, means of keeping a job, means of adjusting to accidents and unemployment, ways to get along with the employer, ways to get along with fellow workers, budgets and banking, ways to travel in the city, suggestions for living at home or away from home, recreation, personal and group relationships, and citizenship.

The ordinary child learns many of these things in the process of living. For the retarded, however, the mastery of these fields of knowledge and skill cannot be left to chance. This is true both because of the way the retarded learn and because service jobs, for which the majority of the retarded are best fitted, are more dependent for success upon general characteristics than upon the specific skills usually associated with vocational training. This training cannot be put off until the retarded is chronologically and socially mature enough to think of job seeking. Many of these skills must be consciously sought by teachers through careful grading and good teaching until they become in the children automatic responses to specific situations. In this regard the Committee on Special Classes of the White House Conference made two significant statements:

(1) "Subnormal [retarded] children obviously cannot acquire as much in quantity as the typical group and they also require more time for any given quantity than is the case with typical children.

(2) ". . . the lower the degree of potentiality the earlier should attention be centered on vocation. The subnormal [retarded] child can be put at productive work earlier than the child who needs more time for preliminary training but he should be prepared for his work as long as possible."

Few things are more certain than the fact of human variation. In one sense there is no such thing as an absolute standard of normalcy. People vary in stature, in color, in weight, in glandular balance, in visual acuity, in emotional balance, in mental ability. Some of these variations have a genetic basis or at least a prenatal basis; others arise largely from environmental circumstances. Most are conditioned by a complex interrelationship of prenatal and environmental factors. These differences account for much of the richness of life and also for many of its problems. The problem, therefore, for educators as well as for society as a whole, is to find a reasonably workable way to prevent the variation which is destructive in result without weakening the variation which is constructive. Obviously, no one knows with certainty how to do this. It is quite sure, however, that it must be attempted. In fact, it is being attempted, though far too seldom consciously and under an intelligent plan.

Like society in general, school people move with much more directness and with much more assurance where the object is concrete. Thus, the great majority of educators would attempt consciously to provide adequate school lunches to the undernourished or for the malnourished. They would provide showers, well-lighted rooms, recreational facilities, even competent vocational guidance and placement workers. There would be far less unanimity and assurance, however, in making realistic provision for the building of socially acceptable intellectual and emotional patterns. We not only know less of how such patterns are made; we are far less certain of the patterns we desire to make.

Throughout his life the individual is engaged in balancing (a continuing task) what he is (his tools, his spirituality, his thought processes, his emotional desires, his physical needs) against what he must do (his problems, human relationships, and physical surroundings) in order to achieve the greatest possible personal satisfaction at the level of his development (survival,

physical enjoyment, gregariousness, aesthetics, logic, social contribution). More simply, every maturing individual is accommodating his changing body to his expanding responsibilities.

For at least 90 per cent of adolescents, achieving acceptable economic status implies achieving economic self-sufficiency. The young person without further training and experiences is expected to be able and willing (that is, emotionally able) to earn his own living in open competition with all others. It is easy of course to overestimate the importance of this fact, but the practice, among curriculum builders especially, is to underestimate it. Yet this and other adjustments or accommodations listed in this article are the required learnings of young people. Whatever the ostensible goals set up by educators, these are the learnings with which the school is expected to give great help. In other words, schools were established and are maintained to help young people achieve such competencies more easily. In a very real sense the nominal goals are merely the media by whose mastery school people have thought the required learnings could be achieved.

Almost all individuals fail sometimes; a few fail so repeatedly and so grossly that they must be considered as problems. Some of the problem children are not school problems in the ordinary use of the term. But before we can determine whether or not a child with a gross problem unmet is a school problem, we must decide what society reasonably can expect from a school. If a school is responsible only for giving pupils academic proficiency, then a school problem is only a child who is not making "normal" academic progress. If a school is responsible only for helping a child to make immediate adjustments, then even the child who acts "acceptably" only when nothing is demanded of him is not a school problem. If, however, a school is responsible for helping an individual to make a total adjustment, both while in school and throughout his life, then the school problem is the child who is not making reasonable progress along all the lines—spiritual, social, physical, emotional, vocational, and academic—which he presumably will need throughout his life.

Educators have recognized the desirability of modifying school programs to meet the needs of individual pupils. Too often, however, such modifications have been mere progressive "waterings down" of subject matter rather than an introduction of new content not technically academic in nature. The general order in which the school has placed its emphasis has been as follows: (1) academic proficiency; (2) occupational competency (largely the concern of vocational schools and commercial departments); (3) competency in social adjustment.

It is clear that for a great many pupils this order of emphasis cannot be justified, and that for at least 20 per cent of the pupils it must be reversed if education is to help such individuals appreciably. The three competencies naturally must be integrated, but the first objective must be to develop citizens capable of making total adjustments as readily and as satisfactorily as possible. This is necessary to ensure comparative maturity, both social and occupational, since almost every study which has been made of job holding and success reveals the need for personal qualities that will enable a person to make adjustments socially acceptable.

As a second objective, the schools must seek to develop economic and occupational competency of a type which will permit the young person to find a place where he can succeed in the world of work. This concern with the vocational objective does not mean that "occupational adjustment is the sole goal of the school program. Rather, what is meant is this: occupational adjustment is one of the inter-related, individual goals of the accepted program. . . . Education which does not seek occupational adjustment is incomplete." [1]

Academic competencies as such must take third place in school objectives for most pupils, especially when school goals are considered in terms of present day courses of study and curriculums. It is estimated that one child out of five of school age is not capable of benefiting at 16 years of age from a school program requiring mastery of academic skills beyond the sixth-grade level. With maturational promotion in effect in the elementary and junior high schools, it must be expected that senior high schools will have approximately this percentage of slow learners in their student bodies.

The retardation encountered will be the result of many factors, heredity being only one. Whatever the cause of the retardation, however, no practical change of teaching method will enable this group of pupils to master academic skills beyond the sixth-grade level. The adaptation of schooling to their needs and abilities involves far more than a meshing of educational guidance goals with existing grade levels and a slowing down of the rate of presentation. Instead, there is necessary a reconsideration of skills from many levels. A lower-level job from an economic standpoint may require the inclusion of certain skills from the standard eighth-grade level and the omission of others on the third-grade level. For example, certain jobs have certain vocabularies. A boy may be reading at the fourth-grade level; he may need to know 20 words at the eighth-grade level. He must be given these words irrespective of his reading level. In point are the words on social security and job applications. It should be stressed, however, that pupils are limited not only with respect to the degree of difficulty which they can master, but also with respect to the amount they can master even at the levels they can achieve. Thus, in order to get the time to teach—not merely to present—the words on a social security blank, it may be necessary to omit fractions with denominators above four, even though such fractions may be standard fifth-grade content and within the grasp of students capable of doing fifth-grade work. There must be long-term planning to ensure the teaching of first things first, both in the sense of order of presentation and in the sense of individual life needs. If it is a question of teaching a pupil to master fractions or to get along with his employer, the latter must be taught. If a pupil cannot be taught to get along with both the boys in his block and the boys halfway around the world, then the pupil must be taught to get along with the boys in his block.

The schools must be equally certain that the content is meaningful and challenging to the pupils. It would be absurd to use books of

[1] R. H. Hungerford and C. J. De Prospo, "Occupational Education and the Curriculum," *Occupational Education*, February 1946.

ninth-grade or even sixth-grade difficulty with a boy capable at the time of using only a fourth-grade book. It is equally absurd to use books with content, particularly social content, much below the pupil's needs and abilities. Thus, for a fourth-grade pupil of 15 years of age, a fourth-grade reader built around the interests of 11-year-old pupils may be almost as bad as a sixth-grade reader. The latter, the pupil is incapable of using mentally (for the time being); the former, the pupil is incapable of using for psychological backgrounds. Help can come from learning about the Eskimos only if such studies deal with the problems of the Eskimo father in bringing in enough blubber, making the man next door keep the dogs chained, and helping a son to realize that life is more than blubber or dogs. A real understanding of actual Eskimo life might be helpful, though probably not as helpful as content nearer home would be; generalizations about trivialities of Eskimo life cannot be justified.

It is the business of the school to give the individual, insofar as possible, all the experiences necessary for building the attitudes, skills, and habits he must use, at least in his beginning independence. Anything which does that is learning. Individualization of instruction is concerned quite as much with content as with technique. There is necessary a thorough reconsideration of the meaning of school goals. Even for the most retarded of the school group it is not necessary to omit or change any of the cardinal aims of education. It is necessary to reinterpret the meaning of applying goals to individual abilities and needs.

Occupational education is an inclusive program. It begins when the retardate enters the special class and does not cease until the need has ceased, however long that may be. It is an inclusive program also because it consciously attempts to prepare the child for many possible life situations. All encounter depressions, booms, war, and peace, and a complete education cannot leave an individual unprepared for any. This is true for all individuals; it is especially true for those who by very definition are unable to make quick and efficient adaptations to new situations.

Occupational education is not a technique of teaching. It is comparable to the social studies in that it provides a series of occupational-social skills leading toward social maturity. Because of its nature, however, it tends to become the interest core for all teaching in a special class. Occupational education is the content of instruction. As such it may be taught by any method, although it is believed that the activity or unit approach will produce the best results.

A continuing tendency in special education has been to try to lift the child above his capabilities. After viewing the total pattern of the individual in relation to this total life, occupational education teaches the possible skills basic to total adjustment. With this point of view, academic skills are relegated to their proper place, becoming only one part of the cores used for instruction.

All teaching presupposes the existence of goals based, at least suppositionally, upon an awareness of pupil needs (including real interests) and abilities. Occupational education consciously accepts responsibility for meeting pupil needs in the order of urgency. It does not limit pupil needs, but neither does it suppose that education occurs through osmosis. A boy does not become a worthwhile member of society by living in a town containing worthwhile members of society. A school has the responsibility of providing each pupil with the curriculum which will enable that pupil to function in school days and in adulthood in the most effective and happy way possible.

MENTAL SPINE, in anatomy, the single or double tubercle on each side of the body of the mandible, for the attachment of the genioglossus and geniohyoid muscles.

MENTAL TESTS. Historical Background.—Modern psychology has been aptly

characterized as an experimental science, and its preoccupation has been with the typical human being. There were trends, however, as early as the 1880's, that bore in the direction of emphasizing individual differences. One was the clinical study of abnormal personalities, and eventually some of the hospital psychiatrists turned to the psychologists and their laboratory instrumentation for many of their methods of examination.

Meanwhile, out of the laboratory experiment the mental test developed; for once experimentation had furnished a set of findings drawn up as laws about people in general, then the individual man could be examined and compared with man-in-general. When an experimental technique was used to determine a given person's particular ability or trait, it became not a psychological experiment, but a mental test. At first, the traits tested were mainly: reaction time; sensory keenness and sensory discrimination; memory abilities; motor accuracy, steadiness, and speed; imagination; word-association; and attention.

At the beginning of the 20th century attempts had been made at combining tests such as these and others to see which combinations might be fruitfully used. At Columbia University, J. McKeen Cattell was applying a battery consisting of a wide variety of laboratory-derived tests to the entering freshman and again to the graduating seniors, to see what changes due to age or to college environment might be brought to light.

Tests of General Intelligence.—Progress in the measuring of special aspects of psychological equipment became overshadowed by one achievement in particular. This was the successful combining and scaling of different tests to form a measuring rod for general intelligence. In 1905, 1908, and 1911, Alfred Binet (1857–1911) and Théodore Simon (1873–) devised a method, which would be more valid and more time-saving than were the teachers' judgments, for identifying those children in the schools of Paris that should have special attention. Their scale consisted essentially of series of problems and questions, to answer which demanded the exercise of "general intelligence." They were designed not as a test of the child's knowledge derived from school or home training, but as a test of his native capacity to acquire such knowledge. The child might be asked to follow out simple commands, to draw copies of complicated designs, to combine disarranged words into a sentence, to name some objects shown to him, or to tell what he would do in certain everyday situations described by the examiner. The tests were so graded that the easiest lay well within the range of the ability of the average 3-year-old, while the hardest taxed the ability of average adults. The scaling of these tests was done empirically, i.e., was based upon found results with Parisian children of all ages. For example, if, when tried, a given test was successfully passed by two-thirds to three-fourths of the 9-year-olds, but by a much smaller ratio of the 8-year-olds and a still smaller ratio of the 7-year-olds, it was then set up as a suitable test for "9-year-old intelligence." The tests accepted as best differentiating ability of the average 8-year-old were placed together, those for the average 9-year-old were placed together, and so on until for most age-years, a set of five tests was available; the whole series were finally combined into one scale, from age 3 to age 15 and to adult. By such a measuring rod it became possible to find out whether a given child tested was "at age," i.e., normal, or was retarded or superior.

The practical value of the Binet tests was not long in becoming recognized outside France. In America clinical psychologists were prompt in setting about the task of revising Binet's particular tests to the language and experience-background of the average American child, and of improving the scale and the procedures of administering and scoring. The scale most employed today is that constructed by Lewis M. Terman and Maud A. Merrill, which is the 1937 revision of the "Stanford-Binet" examination. They adopted from Wilhelm Stern the method of indicating the *relative* brightness of a child by his "intelligence quotient" or "IQ," found by dividing his "mental age" by his "chronological age." If a subject's IQ is around 100 per cent, then he has tested as somewhere near the average of children of his chronological age—he is of normal intelligence. If his IQ is 75, he has been found able to pass tests only of much younger ages than his and he is classed as mentally subnormal, or perhaps feebleminded.

Interest in intelligence testing has inspired a truly enormous amount of work. Most of this work has been based upon the use of tests as well accepted measures to determine what relationships may be found between intelligence and some other variable such as age, nationality, blood kinship, home status, occupation, and innumerable others. A few of the researches have been in the direction of critical inquiries into the nature of intelligence itself. Binet, and most others who have adopted his scale, have assumed that what the tests purport to measure is largely a native trait, intrinsic to the individual person. The point is reflected in the notion that the IQ of the same individual remains very closely the same throughout childhood. Thus, a boy at 5 years who tests 6 years in mental age, and so has an IQ of 6/5 or 120, will, when 15 years old, continue to have an IQ of 120, and will be mentally as bright as 18-year-olds. Obviously, this predictive function of the IQ has tremendous importance. There is a controversy, however, between those investigators who claim to have demonstrated that a child's IQ can be raised many points by furnishing him a stimulating environment and careful teaching in early years, and those who insist that such claims greatly exaggerate the possibilities.

Certain limitations in the Binet method of examining for intelligence have been recognized, and have led to the development of supplementary tests. (1) It cannot be as successfully employed with adults as with children. This arises from the fact that Binet originally standardized his tests only up to and through the age of 15 years; and the Stanford-Binet of 1937, though adding three more levels of brightness, still assumes 15 years as the "average adult" level. Then, too, the very content of many of the test items is unlikely to elicit the desired interest on the part of adults. Also many of the tests put a premium on the speed factor, whereas the slowing down in mental operations in later maturity has been found to be at no cost in accuracy. For the examining of adults on the other hand there are the *Wechsler-Bellevue Intelligence Scales* or the *Army Individual Test*. With these scales the final score of brightness is not cal-

culated from mental age values of tests passed, but from the total number of points made on all tests, this total being then restated as a distance (in "standard deviations") above or below the average score made by adults of all ages. These have two advantages. The component tests fall into two general sorts: the verbal test and the performance test, which makes it possible to compare an examinee's facility in using words and symbols with his ability to manipulate objects and to perceive designs. Furthermore, the patterns of high and low scores on the respective component tests of the Bellevue scale vary characteristically with certain psychiatric groups (as the schizophrenic, the neurotic, the defective), so that not only brightness-level but clinical type of deviate can be recognized.

(2) The Binet type of test depends in part upon the examinee's ability to use language, oral and written; yet there are classes of people, whom it may be desirable to examine, who are illiterate or deaf, or who are unfamiliar with the English language. The oldest and best-known of the *performance* tests is the *form board* type, consisting of a baseboard bearing holes of varying shapes into which the examinee is instructed —by wordless hand motions if need be—to fit the appropriate blocks from among those supplied him. The *picture assembling* test is much like the popular jigsaw puzzle, with pictured objects or events which require some understanding and interpreting of them in order to completely assemble them. There is the *block design* test in which the examinee is shown a colored pattern and is instructed to copy this by putting together cubes with different colored faces and half-faces. Quite different is the *cube imitation* test: four cubes are set in a row before the subject, then the examiner taps them with a fifth cube in some standardized irregular order, and the subject is bidden to do likewise.

(3) The Binet method of intelligence measurement cannot be employed to test more than one individual at a time. This has led to the develop of *group* intelligence tests.

Group Tests.—The initial spurt of interest in group tests was occasioned by the recognition of their practical value, when the United States entered the First World War, in sorting out army recruits of varying levels of intelligence for promotion, discharge, special training, and other differential assignments. These men were drafted in such numbers that testing them individually proved unfeasible. In a group test the examinees are provided with printed booklets containing a variety of tests, each usually printed on a separate page and so arranged that it can not be seen in advance of or after the time during which work is to be done on it. The examiner uses a series of signals by which all examinees' starting and stopping of tests is controlled in concert. Each test is a series of questions or other items calling for penciled answers.

Just as in individual examining so in group examining there was seen to be a need for tests of nonlanguage or performance types. To meet this need there were developed printed problems that utilized designs rather than words. Since the First World War there has been a heavy output of group intelligence tests of both language and performance nature, including the *Army General Classification Test* employed in the Second World War.

Results of Intelligence Testing.—Just as the origin of intelligence tests lay in practical school demands, so their widest usefulness has been in connection with educational problems. For one thing, they have been quite widely employed to differentiate the children in school classes into the superior, average, and inferior sections; and over a wide area the differential treatment of the sectionized grades has obtained gratifying results. It should be pointed out that in dealing with the individual child, administrators recognize many factors other than native intelligence as contributing to his school success, such as health, home environment, and industry. Intelligence tests do not measure ability in all school subjects equally well; their results have been found to correlate better with grades made in composition, reading, and arithmetic, e.g., rather than with grades made in handwriting, handwork, drawing—or even spelling.

Group tests of the intelligence test type—though not so labeled—have been in well-nigh universal use in the induction of college freshmen, furnishing data for later reference in cases of disciplinary action or of counseling.

The greatest use of tests of intelligence, after educational and after military needs, is in vocational guidance. It is assumed that insofar as the different occupations and trades demand of people successfully pursuing them, different ranges of level of intelligence, then to learn the level of a given young man or woman is very material to guiding him successfully. This has been borne out in a very general way. However, success in a given occupation obviously depends upon so many other factors—interests, special aptitudes, personality makeup, and others —that the tests of general intelligence may be said to have more of an eliminative than a positive selective value.

Achievement Tests.—The impression made on psychologists and educators by the successes of the intelligence test movement led rapidly to the adoption of similar objective methods for measuring other abilities and traits. The impact upon school subject examinations was shown by the adoption of various test forms that freed their scoring from the influence of subjective impressions on the examiner's part. They included the answer of "true" or "false"; underscoring the correct answer out of alternatives; filling in a blank space with the correct word, or matching the relevant items in two arrays. These achievement tests are used to measure what level of facility or range of information the examinee has achieved in some particular area, as algebra, Italian, economics, or a nonacademic subject.

Aptitude Tests.—Another direction taken in the widening application of objective testing methods has been in the measuring of characteristics of a person that predict his ability to acquire, with training, some particular skill or knowledge. A celebrated battery of aptitude tests is that for *musical* talents devised by Carl E. Seashore. He has shown that "ability in music" really involves many components in a complex hierarchy, and for most of these he provided specific testing procedures. Phonograph disks are used to produce the sounds used in testing ability to discriminate differences in pitch, intensity, time interval, timbre, melody, and rhythm. The scores derived from these and other tests are then represented graphically as distances from a zero line, the resulting "profile" presenting a

kind of picture of the examinee's various musical talents. Musical tests have been widely employed to direct attention to pupils who have unsuspected abilities calling for musical training, and they have also shown that in others musical training is an unwise investment. Other tests of music furnish vocabulary and question tests to measure musical knowledge.

Aptitude for *art* training has been tested in a variety of ways. One is by showing pairs of uncolored pictures or sets of four designs, the examinee to indicate his preference in each case, and then comparing these judgments with those previously obtained from art authorities. Many other art aptitudes, such as color preference, have been subjected to measurement.

Aptitude testing has shown much advancement in examining capacity for *mechanical* training. Some tests put a premium on the subject's ability to "get the hang" of a mechanical device, by asking him to assemble correctly into a working unit the separated parts of a bicycle bell, of a monkey wrench, of an electric light socket, or some such device. Other tests are directed at manual dexterities, as those involved in handling a complicated form board or stacking together some "wiggly" blocks. Then there are paper-and-pencil tasks, such as the kind that asks which pictured tool (screw driver, wrench) is used with each pictured object (a nut, a bit); or the kind that demands the quick putting of dots into small circles, or that involves counting how many blocks touch other blocks in a pictured pile of them.

Tests of other vocational aptitudes have been, and are being, developed. Tests of *clerical* aptitudes usually consist of operations not essentially different from those called for on the paper-and-pencil group intelligence tests; but they are directed to details that are especially relevant to the work of a business office, such as checking numbers or matching names.

The interest in vocational counseling, as well as the need which has been felt for sifting applicants for admission to the professional schools, have supported attempts to apply principles of aptitude measuring to the *learned professions*. The validation of these principles has been measured by comparing the scores of such applicants with the grades later made by the examinees in the professional school studies rather than with the degrees of success achieved still later in professional practice; and the value of these tests has been limited on the whole to selecting the persons who will do well in the professional fields in question.

In *medical aptitude* tests, the traits covered vary considerably; but taken together, they include tests of such things as knowledge of scientific facts, visual imagery, logical reasoning. Medical schools are using these tests to some extent for active selecting of candidates, but they are also maintaining a research attitude toward the question of their ultimate validity. There has not been as widespread acceptance of aptitude tests for admission to law schools as for admission to medical schools. For the study of engineering, aptitude tests have been devised ever since the end of the First World War; but there has not been persistent interest in comparing, validating, and standardizing the manifold available tests on a nationwide scale. Mathematical ability seems to be the most adequate single measure upon which ability to do the work of the engineering schools can be predicted, with facility in spatial thinking running second.

Interest Tests.—Success in an occupation certainly depends upon more than one's native ability developed by training; it depends upon his interests in many different directions. Consequently, aptitude tests frequently are supplemented by interest inventories. The examinee may be furnished elaborate lists of items concerning amusements, school subjects, people's peculiarities, personal possessions, and the like, and he is to indicate for each item whether he likes, dislikes, or is indifferent to it. The results are then studied to see whether or not the pattern of the examinee's likes-dislikes resembles that previously obtained from successful engineers, or life insurance salesmen, or other vocational groups. Where there is high correspondence, it is to be concluded that—capacity and training granted—there is evidence that the examinee would be happy in that occupation.

Personality Tests.—The great contemporary interest in problems of the total personality has led naturally to the development of approaches to the measuring of *personality*. But that word has many meanings; the approaches therefore are diverse.

The *questionnaire-inventory* method, developed during the First World War by Robert Sessions Woodworth (q.v.), has been adopted in myriad forms. Essentially this is not a test in which the subject actually faces a problem or situation, but a test which consists of a list of questions which the subject answers in the first person; e.g., "Are you easily moved to tears?" "Are you touchy on various subjects?" "Are you slow in making decisions?" In a form much in use, R. G. Bernreuter has picked 125 questions from many of the more successful inventories and recombined them. By applying different scoring keys which assign different weights to the various answers, the subject can be scored on six personality traits: neurotic tendency, self-sufficiency, introversion-extroversion, dominance-submission, self-confidence, and sociability. It can be seen readily that in the adoption of such self-questioning methods, whatever their internal consistency, their validation (the faithfulness with which they do measure what they purport to measure) must be a persistent problem.

Other scales in much use, especially by industrial concerns, assume certain "components" of the personality for which the tests may be scored: hysteroid, cycloid, schizoid, epileptoid, hypochondriacal, masculine-feminine, and others. Such terms come from the psychiatric hospital, and this use here recognizes that the deviations and eccentricities of mental illnesses are after all only exaggerations of variations to be found among the normal.

In clear contrast with the personality tests which limit the subject's responses to previously drawn-up alternatives and which consist of many discrete items, is the *projection* type of personality test. Therein the subject is free to react as he pleases—and this yields insight into his desires, phantasies, emotionality, dominant interests. The Swiss psychologist, Hermann Rorschach, seized upon the familiar ink-blot exercise as a way of revealing the profounder characteristics of a patient in his way of *seeing* or apprehending the blots. Standardized printed blots are presented one at a time to the individual for his

oral responses. (In a form adapted to groups, the blots are thrown upon a screen and the examinees write out their responses.) Does the examinee see things as a whole, or does he emphasize the details? Is he influenced more by form, by movement-sensations, or by coloring? Does he tend to see human beings, animals, plants, or landscapes? Are his responses individual with him, or much like those of other people? This may look like a piecemeal, item-by-item, analytic sort of approach. It is far from that. All the tabulated details are arranged so that the skillful clinician can inspect them, not by adding and subtracting, but by apprehending them as a whole. It is not unlike the way one looks at a picture; and it should lead the clinician to a true picture of his examinee as a total personality—his expressiveness, interests, talents, temperament, and even his philosophy of life. The idea is not unfamiliar in daily life; one often speaks of knowing his friend—not as a series of itemized details but as an indivisible unique personality. The claims of those who use and adapt the Rorschach method are broad and ambitious; nevertheless it is growing in favor and in use.

A newer projective technique, the "thematic apperception" test, employs a series of pictures, each depicting an ambiguous dramatic human event. The examinee is instructed to build up some fictional story illustrated by the picture, with preceding and subsequent events. In doing so he may be expected to read into the material some of his own personal problems and underlying strivings, the stories when taken together revealing a unifying thema. As is obvious, insight and judgment is demanded of any examiner employing this technique.

Among the most important things in the organization of a man's personality are his *value* attitudes. The esthete, the man-about-town, the sanctimonious, the money-mad, furnish cases of special channeling of interests into specific areas. A method for determining the relative strengths of these different value-species within an individual consists of questions on specific problems or situations, the answers to which will reveal the examinee's appreciations to be more weighted by theoretic, economic, social, political, religious, or esthetic considerations.

In General.—The foregoing account is of necessity selective. Of the hundreds of mental tests in actual use, only some examples of the more distinct kinds could be mentioned.

Nor has space permitted adequate mention of the manifold applications of mental tests to education, to vocations, to military service, to hospitals, and to social-welfare work in general.

JOHN FREDERICK DASHIELL,
Kenan Professor of Psychology, University of North Carolina.

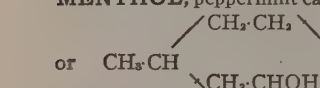
MENTCHIKOF, or MENSHIKOV, Alexander Danilovich, Russian soldier and statesman: b. Moscow, Nov. 6, 1672; d. Berezov, Siberia, between November 1729 and February 1730. He was of obscure parentage, but succeeded in entering the service of Prince Lefort, the favorite of Peter the Great, later discovering and thwarting a conspiracy against his patron's life. After serving in the campaign of Azov, he accompanied the Czar on his trip through Holland and England, and on the death of Lefort became his chief adviser. He was created field marshal and prince by Peter, and prince of the German Empire by Leopold I, and during the absences of the Czar acted as regent. During the campaign of 1706 he defeated the Swedes at Kalish, and in 1709 was largely instrumental in securing the victory over Charles XII at Pultowa. In 1710, as commander of the Russian forces in the north, he took Riga, occupied Pomerania and Holstein, and conquered Stettin. His arbitrary acts, however, finally resulted in his court-martial by Peter, though the death sentence was commuted to fine. He was one of the principal factors in the accession of Catharine I to the throne (1725–27), and till her death was all-powerful, and even after Peter II succeeded to the throne he had absolute control of the government. He was about to marry his daughter to the young Czar when he was suddenly overthrown by Vasili Lukich Dolgoruki (1670–1739) and exiled to Siberia by Peter II in September 1927. His great-grandson, PRINCE ALEXANDER SERGEEVICH MENSHIKOV, b. Sept. 11, 1787; d. May 2, 1869, took a prominent part in the campaigns against Napoleon (1812–15) and the Turks (1828–1829). He was governor general of Finland in 1831 and in 1854–55 he commanded the Russian naval and military forces in the Crimea. He is noted for his conduct of operations in defense of Sevastopol.

MENTHACEAE, sometimes known as *Labiatae*, a family of dicotyledonous herbs or shrubs distributed mainly in temperate climates. The species, of which there are more than 3,000 grouped in about 150 genera, are characterized by four-cornered stems; opposite, exstipulate leaves; mostly two-lipped flowers generally in whorls, cymes or heads; and one to four achenes in a persistent calyx. They are noted for their volatile oils, which in many instances are of economic importance either as perfumes or as flavorings. Some species are cultivated for ornament, but probably the best known are those which have been used for centuries for flavoring food, such as sage, thyme, savory, marjoram, mint, balm and basil (qq.v.). The kinds used most frequently in perfumery are probably lavender, rosemary and patchouli. One species, variously known as Chinese or Japanese artichoke, chorogi and knotroot, *Stachys sieboldi*, yields edible tubers which are eaten raw or cooked in Asia, France, and to a small extent in the United States. Many labiates have at some time been reputed medicinal but are now rarely used except to disguise

the taste of disagreeably flavored drugs. The best-known genera represented in the United States are *Nepeta* (catnip), *Mentha* (mint), *Origanum* (marjoram), *Salvia* (sage), *Thymus* (thyme), *Marrubium* (horehound), *Satureia* (savory), *Lavandula* (lavender), *Monarda* (horsemint), *Ocimum* (basil), *Melissa* (balm), *Scutellaria* (skullcap), *Lamium* (dead nettle), *Calamintha* (calaminth), *Teucrium* (germander), and *Trichostema* (blue curls).

MENTHENE. See METHANE.

MENTHOL, peppermint camphor, $C_{10}H_{19}OH$,



or $CH_3 \cdot CH(CH_2 \cdot CH_2 \cdot CH \cdot CH(CH_3)_2) \cdot CH_2 \cdot CHOH$

is the chief solid constituent of the Japanese and Chinese peppermint oil (from *Mentha piperita* Linne, or *Mentha Arvensis*). American and English oils contain menthol in much smaller quantities, and the menthol obtained from these sources is said to differ from Chinese or Japanese menthol in its crystalline structure.

The commercial product is chiefly obtained from the Japanese oil of peppermint, which sometimes contains from 70 to 90 per cent of menthol. For the extraction of menthol the oil is cooled to a very low temperature, when prismatic crystals separate out. The yield is considerably increased by subjecting the peppermint oil to fractional distillation and then cooling the residue. A number of substances are sometimes used to adulterate the commercial product; among these may be mentioned hydrated magnesium sulphate, paraffin, wax, thymol and various inorganic compounds. The pure substance should possess a sharp melting point and should completely volatilize when heated on a water-bath in an open vessel. Menthol separates in long prismatic crystals. It melts at 43° C., and boils at 212° C. The crystals possess a strong peppermint odor and a cooling taste. It dissolves readily in alcohol, ether, chloroform, carbon bisulphide, strong acetic acid and in a number of oils. Its solubility in water is very slight but the water solution possesses the odor and taste of the substance.

The molecule of menthol contains three asymmetric carbon atoms, and a number of stereo-isomerides are possible; the commercial product consists mainly of the laevo modification. Menthol exhibits the properties of a saturated secondary alcohol. Careful oxidation with chromium trioxide converts it into the corresponding ketone, menthone. With acids it yields esters. With phosphorus pentachloride it forms menthyl chloride. Heated with phosphoric anhydride or zinc chloride it forms menthene, $C_{10}H_{18}$. With copper sulphate it yields cymene, and with hydriodic acid, in the presence of phosphorus, it forms hexahydrocymene.

Menthol acts as a mild local anæsthetic. In the form of cones or in solution in various solvents it has been used as a remedy for neuralgic headache, toothache, catarrh of the nose, asthma, diphtheria, diarrhœa, sciatica and tuberculosis of the bone. Sometimes it is also employed as the chief ingredient in atomizers, inhalers, toothpastes, ointments, liniments, and in a number of preparations for internal use.

V. S. BABASINIAN,
Professor of Chemistry, Lehigh University.

MENTONE, mĕn-tō'nĕ (Fr. MENTON, mŏñ-tôñ), France, a seaport town and health resort on the Mediterranean, in the department of Alpes-Maritimes, near the Italian frontier, and 15 miles northeast of Nice. It is charmingly situated on a promontory about the middle of a bay five miles in circuit, encircled by abruptly rising hills. The ancient walls of the feudal town are still standing, and there the streets are dark and crooked. The new part of the town, with numerous fine villas, stretches along the base of the hill on which the old part is situated, parallel to the sea. The climate of Mentone is mild and equable; it is rare that the thermometer descends as low as the freezing point, or rises higher than 86° F., hence making Mentone a favorite resort for persons in delicate health. There is a considerable trade in fruit, in flowers and leaves used in the manufacture of perfumes, and in olive-oil. The town of Mentone belonged to the principality of Monaco from 1346 to 1860, but in the latter year was ceded to France. In the vicinity, but on Italian territory, are the grottoes of Baoussé Rousse, popularly known as the Caves of Mentone, famous for the valuable evidences of prehistoric man that they have yielded. Pop. (of commune) 18,000.

MENTOR, according to Greek legend, the faithful friend of Ulysses, who entrusted to him the care of his domestic affairs during his absence in the war against Troy. The education of the young Telemachus fell to his charge, and when the latter set out on his voyage in search of his father Minerva accompanied him under the form of Mentor (Odyssey, ii, 390; iii, 12, etc.), acting the part of a prudent and experienced counsellor to the young hero. This character of a sage adviser is more fully developed in the Télémaque of Fénelon, in which Mentor plays a conspicuous part.

MENZALEH, mĕn-zā'lĕ, or **MENZALA,** Egypt, a large lake or lagoon (one of several at the Nile delta), extending from Damietta to the Suez Canal, and running parallel with the Mediterranean, from which it is divided by a narrow slip of land, from 2 to 12 miles in breadth. Length of the lake from northwest to southeast, about 50 miles; average breadth, about 20 miles. It receives the Pelusiac and Tanitic branches of the Nile, and communicates with the sea by three openings called Dibeh, Gemileh and Om Farejeh. The lake is of comparatively recent origin, and covers what was a fruitful district of the delta, having formed through neglect of the dams. There is a small town of the same name on the south side of the lake. The Suez Canal cuts into its eastern edge from north to south.

MENZEL, Adolf Friedrich Erdmann von, German artist: b. Breslau, 8 Dec. 1815; d. Berlin, 9 Feb. 1905. In 1830 his parents settled in Berlin, where his father had a lithographic studio, and where the son studied a little in the academy and more by himself. At 18 he published a cycle of lithographs called 'An Artist's Wanderings,' which immediately attracted attention; four years later he had begun to draw historical scenes from the past of Brandenburg and had commenced painting in oils with 'Checker-Players' (1836) and 'Judgment' (1837). About the same time his work as an illustrator opened up with the 400 pictures

for Kugler's 'Frederick the Great' (1840), in which Menzel showed himself original, dramatic and historically correct. This vein he followed out in his 200 illustrations for the 'Works' of Frederick the Great, and in 600 more accompanying a work on the army of Frederick the Great (1856); as well in his oil paintings, a dozen or more, of various scenes in Frederick's life. A trip to Paris in 1867, so the French critics claim, worked a change in Menzel's methods, so that he applied himself more to problems of light and shade. After 1890 he used color less and less and in his pencil drawing broke away from mere line to the use of a cloudy treatment. He was one of the greatest of German artists of his day; and in 1899 he received the Order of the Black Eagle, conferring hereditary nobility. Apart from his historical pictures, mention should be made of the 'Modern Cyclops' (1875), the interior of a Silesian rolling mill, with excellent lights, and of social satires like 'Carnival Morning' (1885). Consult Jordan, 'Das Werk Adolf Menzels' (1895); and lives by Sondermann (1895), and Knackfuss (1897); Singer, 'Drawings of Adolf von Menzel' (London 1908).

MENZEL, Wolfgang, German author: b. Waldenburg, Silesia, 21 June 1798; d. Stuttgart, 23 April 1873. He studied at Jena and Bonn, became a follower of F. L. Jahn and the Turnerei, and was for four years schoolmaster at Aarau in Switzerland. In 1825 he returned to Germany, having already made himself known to the literary world by his 'Elastic Verses' (1823). He edited and contributed to magazines, and wrote a very great number of works, poems, romances, histories, criticisms, political polemics and Christian theology. From 1826 to 1848, and again later, he was editor of the *Litteraturblatt* in Stuttgart. His chief writings include histories of Germany (1825), German literature (1827), German poetry (1858) Europe (1853–57), and the world ('Universal History' 1862–72). He also produced a work of mythological research (1842), a book on the pre-Christian doctrine of immortality (1869), and autobiographical memoirs (1876). He was often involved in controversy, assailing with equal zeal theological rationalists and political radicals. His attacks upon Goethe and other authors were fully equaled for virulence by the criticisms upon Menzel himself, made by Heine and some of the younger German writers.

MEQUINEZ, or **MEKINEZ,** Africa, a town of Morocco, 40 miles southwest of Fez. It is one of the capitals and the sultan maintains there a palace. There is a historic mosque and many other fine buildings, especially those of the 18th century, when the town was the preferred residence of Sultan Muley Ismail. There is an ancient city wall with nine gates. There are tanneries and potteries. Pop. 30,000.

MEPHISTOPHELES, mĕf-ĭs-tŏf'ē-lēz, a name for the devil, which has been made popular by Goethe's 'Faust.' He was also a chief character in Marlowe's 'Dr. Faustus.' Goethe derived it from an old popular legend, in which it is spelled *Mephistophiles* or *Mephistophilis.* The etymologies of the word are as various as the spelling. Some suppose it to be an irregularly formed Greek compound from the negative *mē; phōs,* light; and *philos,* loving, thus signifying "not loving the light." Others surmise that it may be derived from the Latin *mephitis* and the Greek *philos,* in which case it will signify literally "loving the mephitic vapors of hell." The Mephistopheles of Goethe has little in common with the devil of the popular imagination. He appears, especially in the original form of the drama of Faust, as a real man of flesh and blood, who only preserves those traits of the popular devil of the Middle Ages which are compatible with a true human individuality — as the companion of Faust, as a selfish and malevolent votary of pleasure, always looking to the real, and bringing back Faust by cold and heartless irony, from barren speculation to the enjoyment of the present life.

MER DE GLACE, mār dè glās, France, an Alpine glacier on the northern slope of Mont Blanc, with an area of 16 square miles and an extreme length of about nine miles. It is formed by the confluence of three branches called the Glacier du Géant, the Glacier du Lechaud and the Glacier du Talèfre and is noted for its beautiful scenery. It ends as the Glacier des Bois whence flows the Arveyron River, in the valley of Chamouni. From the village of Chamouni the Mer de Glace is easiest visited and Mont Blanc ascended. The glacier has an average flow of two feet a day during summer and autumn.

MERAMEC SPRING, an unusually large spring in Phelps County, Mo., about seven miles south of Saint James. The water flows as an underground stream in limestone and emerges as a great spring with a flow averaging 125 cubic feet per second.

MERAN, mā-rän', Italy, a celebrated health resort in Tyrol, charmingly situated on the river Passer, near its entrance into the Adige, at the foot of a hill called the Küchelberg. It is the chief town of a small district of the same name. It consists of an old and a new town, the latter with handsome villas and hotels, and numerous fine residences and old castles in the neighborhood. The old town is mainly on the Laubengasse, which is a long, narrow, winding street. The Polish church and other buildings date from the 14th and 15th centuries. It is believed to have been settled originally in the 9th century. Lying in a sheltered situation on the southern slope of the Alps, it possesses a mild and equable climate, and is much frequented in winter by invalids with pulmonary affections. Permanent population 18,000.

MERCADANTE, Saverio, sä-vā'rē-ō mĕr-kä-dän'tā, Italian composer: b. Albamura, 26 June 1797; d. Naples, 17 Dec. 1870. He studied music at the college of S. Sebastiano in Naples under Zingarelli. From flute and violin he turned to vocal music; won great success with a cantata 'L'Unione delle Belle Arti' in 1818, and with an opera 'L'Apoteosi d'Ercole' in 1819; was made chapel-master of the Novara Cathedral (1833) and director of the Naples Conservatory (1840); and in 1862 became totally blind. He wrote many masses and other ecclesiastical music, such as 'The Seven Last Words'; but is best known for his operas, of which the following, out of a total of 50, should be mentioned: 'Elisa e Claudio,' 'Il Bravo,' 'Il Giuramento,' 'I Briganti,' and 'Le due illustri Rivali.'

MERCANTILE AGENCY, a business enterprise, usually an incorporated company, which agrees to furnish subscribers who pay a yearly fee, with information as to the business responsibility, financial standing and credit rating of business houses, whether conducted by private individuals, firms or corporations. They also sometimes have a department for the collection of debts, and sometimes they sell two or three different services, at different prices. The business originated in the United States in 1837, following a financial panic, it being recognized that it was necessary for business houses to obtain better information in the giving of credits. Lewis Tappan was the founder of the first mercantile agency in New York City. The most important agency is Dun & Bradstreet, Inc., a consolidation of the two agencies which had previously led in the business. Merchants prize good ratings in the agency's large books which they issue usually once a year, and loan them to subscribers for their own use; in these books appear lists of addresses and the kind of business, followed by letters or signs indicating their financial responsibility, their promptness in paying bills, etc. Subscribers are also entitled to send in for special reports, giving more detailed or later information. The agency obtains its information — (1) direct from the parties in question, sending a representative to interview them, and asking for a statement, but in no case indicating who wants to know their standing; (2) by inquiry of the concerns from whom the party buys goods; (3) by exchange of information between other agencies or people likely to know their reputation. Concerns that are noted in the agency books as prompt pay, or as being worth $5,000 or more, are usually spoken of as "rated" houses. The highest rating is usually worth $1,000,000 or more, and prompt pay.

In addition to agencies doing a general confidential reporting business on all classes of business houses all over the country, there are others that confine themselves to a particular industry, as Typo, which reports on the houses engaged in printing, publishing and allied industries. The laws recognize that such exchange of information is legitimate, and essential to the conduct of business on a credit basis, and an action for libel in sending out a bad report will not hold against an agency that conducts its business in a fair manner. However, the reports have to be made confidential; if promiscuously circulated, they might become libelous. For it unquestionably happens that at times the agencies report concerns as having less money and less standing than they are entitled to, and they can make mistakes. But as long as they try to be fair, and send out their reports under the seal of confidence, the law protects them. Abuse of the system, to revenge, spite or for blackmail, is practically unknown. The agencies are more apt to err in the matter of continuing to rate concerns too high when their financial standing is impaired. When large concerns have failed it has frequently happened that the mercantile agencies had continued to report them in good standing up to the last. Therefore the credit men of the large houses do not pin their faith entirely to commercial ratings, but use other means wherewith to know the truth. In the very large cities there are credit men's associations, where they confer as to ways and means of keeping credits safe. While there is opportunity for better and more accurate reporting as to credits, it is true that the mercantile agencies of America handle their business extremely well, and constitute one of the most important links in the artificial chain between the industries of the nation. Consult Errant, 'The Law Relating to Mercantile Agencies' (1889); Reinhard, 'A Treatise on the Law of Agency' (1902).

MERCANTILISM. See ECONOMICS.

MERCANTINI, Luigi, Italian poet: b. Ripatransone, in the Marches, 20 Sept. 1821; d. Palermo, 18 Nov. 1872. Against his inclinations he was intended by his father for the priesthood, but he deserted that vocation before taking orders and turned to school teaching. For a time he was professor of Italian and Latin literatures in Sinigaglia. He wrote a number of patriotic songs, including "I tre Colori," but gained his greatest popularity by the song which is now the Italian national anthem or "Inno di Garibaldi." See GARIBALDI HYMN.

MERCAPTANS (Latin, "taking up mercury") or **THIO-ALCOHOLS,** *in chemistry,* a large class of substances having the same constitution as the alcohols, but differing from them by having the oxygen atom in the hydroxyl replaced by sulphur. They are oily liquids or crystalline solids having an offensive, garlic-like odor, and are all insoluble in water. They possess acid tendencies that are more marked than those of the alcohols, and combine with metallic oxides to form salts which are known as "mercaptides." They combine with especial facility with mercuric oxide, and take their name from this circumstance. Ethyl mercaptan is the best-known members of the series, and it is this substance that is understood when "mercaptan" is spoken of, without further qualification. Ethyl mercaptan, $C_2H_5.SH$, is prepared by acting upon ethyl chloride, C_2H_5CL, with potassium hydrosulphide, HKS; the potassium atom and the ethyl radical changing places as indicated by the equation $C_2H_5Cl + HKS = C_2H_5SH + KCl$. Ethyl mercaptan is a colorless, mobile liquid, boiling at 99° F. It is very inflammable, burning with a blue flame, and it mixes readily with alcohol and ether, though only to a very slight extent with water. Like the other mercaptans, it forms salts with the oxides of the metals, the hydrogen atom that is associated with the sulphur being the one that is replaced by the metal. The mercury salt, $Hg(S.C_2H_5)_2$, may be prepared very readily by agitating the mercaptan (or its alcoholic solution) with red oxide of mercury, HgO. Its formation is attended by the liberation of considerable quantities of heat, and the mercaptide itself is obtained in the form of soapy white scales. All of the metallic mercaptides are decomposed by hydrochloric acid. The mercaptans of fatty radicals all give a fine green color when treated with a solution of isatin in strong sulphuric acid and this reaction (as well as their insufferable smell) is used as a test for their presence.

MERCATOR, mĕr-kā'tĕr, **Gerardus** (Latinized form of GERHARD KREMER, krā'mĕr), Flemish geographer: b. Rupelmonde, Flanders, March 5, 1512; d. Duisburg, Dec. 2, 1594. He studied at Louvain, and became a lecturer on geography and astronomy, making his instruments with his own hands. In 1544 he was arrested for heresy, being liberal in his views. He escaped, but 42 of those arrested with him were burnt alive. Recommended to Charles V, Mercator entered into the emperor's service, and executed for him a celestial globe of crystal, and a terrestrial globe of wood. In 1559 he retired to Duisburg and received the title of cosmographer to the Duke of Juliers. His last years were devoted to theological studies.

Mercator is known as the inventor of a method of projection called by his name, in which meridians and parallels of latitude cut each other at right angles, and are both represented by straight lines, which has the effect of enlarging the degrees of latitude as they recede from the equator. (See CHART—*Scales and Projections.*) The method is convenient in mapping small areas. His first maps on this projection were published in 1569; the principles were first explained by Edward Wright, in 1599, in his *Corrections of Errors in Navigation,* whence the discovery has sometimes been attributed to him. Mercator's *Tabulae Geographicae* (1578) is the best edition of the maps of Ptolemy. See MAP.

MERCATOR, Nicolaus. See KAUFMANN, NICOLAUS.

MERCED, city, California, seat of Merced County, 55 miles northwest of Fresno on U.S. Highway 99 and the Atchison, Topeka, and Santa Fe and the Southern Pacific railroads. Altitude 167 feet. Lying in the San Joaquin Valley, Merced is a trade and shipping center for an extensive agricultural region specializing in farming, dairying, fruitgrowing, and stock raising. Industries of the city include the manufacture of cement, fruit processing and packing, dairy products, and pottery.

The city has a library, sanitarium, county hospital, courthouse, national guard armory, three public parks and swimming pools. Nearby is the recreational center of Lake Yosemite, and Yosemite National Park lies 45 miles to the northeast.

Founded in 1870, Merced received its first charter in 1889. It has a council-manager form of government. Pop. (1950) 15,278.

MERCEDES, mĕr-sā'dĕs, city, Texas, in Hidalgo County, 30 miles west-northwest of Brownsville on U.S. Highway 83 and the Missouri Pacific Railroad. Altitude 61 feet. Located in an agricultural region producing citrus fruits and vegetables, Mercedes is a center for packing, canning, processing, and shipping. The city's industrial production includes packed meat, cheese, clay products, oil and natural gas, and sheeet metal and machine shop products.

In 1949 a 1,840 mile pipe line to the New York region was begun. Founded in 1907, Mercedes was incorporated two years later. Its government is administered by a commission. Pop. (1950) 10,081.

MERCENARIES, mûr'sĕ-nĕr-ēz (also formerly called STIPENDIARIES, stī-pĕn'dĭ-ĕr-ēz), foreigners or others who received pay for their services as soldiers, especially as distinguished from government soldiers or those owing military service to the crown or nation.

Hired professional soldiers appear very early in the history of military organization. Foreign mercenaries were used in the armies of Alexander the Great and the Romans, and in England King Harold (1066) had a body of Danes in his army when he defeated the Norwegian king. These were the famous "housecarls" (from the Anglo-Saxon *hūscarl*) who were hired soldiers originally established in the kingdom by King Canute (1018–1035). William III had for some time a body of Dutch troops in his pay after he became king of England and throughout the 18th century Hessian and Hanoverian regiments were constantly in the pay of the British government for temporary purposes. Hessians fought for Great Britain in the Revolutionary War, and the landgrave of Hesse, who sold his troops at so much a head, received upward of $2,500,000 for Hessian soldiers lost in that struggle.

The most famous of all mercenaries were the Swiss soldiers, who were hired, sometimes by the cantons themselves, over all Europe, and formed many famous body guards. They were long employed by the French monarchs, and the Vatican at Rome still has its Swiss guards.

Other designations for mercenaries are *condottieri* (q.v.), who were Italian troops banded together and hired out to the city states in the Renaissance, and "soldiers of fortune," who pursue a military career for adventure and pleasure as well as for gain.

MERCER, mûr'sĕr, **Henry Chapman,** American archaeologist, antiquarian, and inventor: b. Doylestown, Pa., June 24, 1856; d. there, March 9, 1930. Graduating from Harvard in 1879, he was curator of American and prehistoric archaeology at the University of Pennsylvania from 1894 to 1897, and served as editor for anthropology in *American Naturalist* from 1893 to 1897. He made extensive investigations and studies in anthropology in America, discovering several unknown extinct species, and 1897 to 1917, made and presented to the Historical Society of Bucks County, Pa., an extensive collection of objects illustrating the Colonial and early history of the United States by means of the implements and handiwork of the pioneer settlers. In 1916 he built and presented to the society a fireproof museum for preserving the above collection.

Mercer established a pottery at Doylestown, Pa., in 1898, experimented upon and developed the processes of the Pennsylvania Germans for making and decorating pottery, inventing in 1899 a new method of manufacturing tiles for mural decoration and in 1902 a new process for making mosaics. His writings include *Lenape Stone* (1885); *Hill Caves of Yucatan* (1896); *Researches upon the Antiquity of Man in the Delaware Valley and Eastern United States* (1897); *Tools of the Nation Maker* (1897); *The Bible in Iron or the Pictured Stoves and Stoveplates of the Colonial United States* (1915); *Ancient Carpenter's Tools* (1925).

MERCER, Hugh, American general: b. Aberdeen, Scotland, about 1725; d. near Princeton, N. J., Jan. 12, 1777. Educated as a physician, he served as surgeon's assistant in the army of the Young Pretender at the battle of Culloden. Emigrating in 1747 to America, he settled in Pennsylvania, and resided there, in the

practice of his profession, until 1755, when he volunteered in the expedition led by Braddock to Fort Duquesne. Later he moved to Virginia and at the outbreak of the Revolution joined the Continental army, and attained the rank of brigadier general. He subsequently accompanied Washington on his retreat through New Jersey, and rendered valuable assistance at the battle of Trenton. In the succeeding action at Princeton he was mortally wounded and died a week later. Mercer County, N. J., was named in his honor.

Consult Goolrick, J. T., *The Life of General Hugh Mercer* (New York 1906); *Dictionary of American Biography,* vol. 12 (New York 1933).

MERCER, John, English calico printer and chemist: b. Dean, near Blackburn, England, Feb. 21, 1791; d. Nov. 30, 1866. The son of a handloom weaver, he worked in weaving and cloth-printing shops from the age of nine, making his first experiments in dyeing cloth in 1807 and a few years later inventing several weaving designs. He was mainly self-educated and through his study of James Parkinson's *Chemical Pocket-Book* in 1814, he arrived at his first major discovery: a method of dyeing calico by the use of orange sulphide of antimony. As a chemist in the color shop of the Fort Bros. print works, he introduced into England a method of applying lead chromate as a cloth dye. He contributed a number of other improvements and inventions, and served as a partner in the firm from 1825 until its dissolution in 1848.

Mercer devoted the remainder of his life to his own chemical researches. In the field of theoretical chemistry, he suggested the first rational theory of catalytic action and his most far-reaching discovery was the process, called mercerizing (q.v.), of treating cotton cloth to improve its strength and adaptability for dyeing.

MERCER UNIVERSITY, Macon, Georgia, a coeducational Baptist institution opened at Penfield, Ga., as Mercer Institute on Jan. 14, 1833. Chief among the founders were the Rev. Jesse Mercer, early conceiver and patron for whom the school was named; Adiel Sherwood, D.D., who after coming to Georgia in 1818 established a theological school at his home near Eatonton; and Josiah Penfield, of Savannah, who at his death in 1827 bequeathed a fund for educating young ministers. Additional funds were provided by the Georgia Baptist Convention.

Conceived as a theological and classical school for ministerial students only, Mercer from its opening served a wider clientele; and in 1837 it obtained a charter giving it collegiate rank and changing the name to Mercer University. Thereafter it grew steadily.

During the administration of President Weaver (1918–1927), Mercer expanded rapidly. The campus was extended, new buildings were erected, the curriculum was revised, and nearly three-quarters of a million dollars were given to the institution by Georgia Baptists. Another period of physical growth and curriculum adjustment followed the inauguration of President Dowell. Mercer is now organized as a liberal arts college and school of law, with comprehensive curricula in the humanities, the social sciences, and the natural sciences.

In 1951 the working plant, covering about 65 acres, was valued at $3,191,613 and the endowment was $3,072,604. The plant, which includes three libraries, adequately meets the educational requirements of a student body numbering about 1,000 and dormitory and dining facilities are provided for both men and women students.

The teaching staff numbered 81 in 1951. Degrees conferred are B.A., B.S., LL.B., and M.A. Mercer is fully accredited by the various standardizing agencies, and the work done is accepted by the graduate schools of leading institutions in America and Europe.

MERCERIZING, mûr'sẽr-īz-ĭng, a process invented by John Mercer, of Lancaster, England, for treating cotton fiber or fabrics, first patented in 1851. The process consists of steeping the cloth in a solution of caustic alkali. The cloth shrinks about one-fourth and takes more brilliant colors in dyeing than unmercerized cotton goods. Cotton may be mercerized either in the yarn or in the cloth, and a variety of machines are made for this purpose. Some of these machines operating on the cloth employ a tension to obviate some after-shrinkage. This gives a greater yardage, but it reduces the gloss.

The name has sometimes been incorrectly extended to sizing of cloth to give it a better sheen. True mercerizing gives a luster to the cotton cloth, because the fibers are drawn closer and flattened, presenting a smooth surface that reflects the light. A variation in the caustic soda process is employed to give the modern crimped-of-crepe effects.

Consult Marsh, J. T., *Mercerizing* (New York 1941).

MERCERSBURG, mûr'sẽrz-bûrg, borough, Pennsylvania, in Franklin County, near the western rim of the Cumberland Valley at an altitude of 590 feet. It lies 17 miles west-southwest of Chambersburg and is served by the Pennsylvania Railroad. Situated in a productive agricultural region, it has considerable trade in dairy products and its local industries include a tannery, shirt factory, and lumber yard.

Mercersburg Academy, a well-known preparatory school for boys, had its origin here in 1836 with the founding of Marshall College. When Marshall College was moved to Lancaster, Pa., and combined with Franklin College in 1853, the Theological Seminary and preparatory department remained in Mercersburg. From this Mercersburg College developed and was superseded in 1893 by the Academy. Three miles from Mercersburg is Stony Batter, birthplace of James Buchanan, 15th president of the United States. Buchanan made his home in Mercersburg from 1796 to 1809.

The borough was first settled in 1730 by Scotch-Irish Presbyterians. In 1780 the town was laid out and named after Hugh Mercer, the Revolutionary War general. It was incorporated in 1831. Pop. (1940) 1,763; (1950) 1,613.

MERCERSBURG THEOLOGY, a school of religious philosophy founded by Frederick Augustus Rauch (1806–1841) of the German Reformed Church in 1836, his work being taken up by John W. Nevin (q.v.) and Philip Schaff (q.v.). The name comes from the Mercersburg Theological Seminary of the German Reformed Church, whence the teaching of this system spread. The Mercersburg theology urged that the Church was not a voluntary society of believers but a historic and spiritual growth—an attitude showing markedly less hostility to the Roman Catholic

Church; that old confessions cannot express the modern faith in the Church; that the sacraments are more than symbols; that church worship should be orderly—hence the Liturgy (1858) and Order of Worship (1866); and that religious education is of prime importance.

MERCHANT ADVENTURERS, The Company of, an association of English foreign traders with trading stations in Netherlands cities, also extending to Hamburg and other German ports, which enjoyed special privileges and exemptions similar to those of the Hanseatic League in London. Its earliest charter dates from 1407. It was a private company holding a monopoly of exporting certain manufactured articles, especially cloths, and its members were all subjects of the English crown, unlike the Staplers who included aliens as well as Englishmen and were limited to trading in unmanufactured products, particularly wool. Probably the nucleus of the Merchant Adventurers was formed of members of the Mercers' Company of London. New companies of Merchant Adventurers arose in the 16th and 17th centuries, especially during the reigns of Elizabeth and her immediate successors. These included the Muscovy, Levant, Guinea, Morocco, Eastland, Spanish, and East India companies. The Company of Merchant Adventurers trading to the Low Countries in the 18th century was called the Hamburg Company. From its inception in the early 15th century the company was in continuous rivalry with the Hansa, the German group that for centuries had monopolized the North Sea trade. This was intensified in 1545 when the Emperor Charles V cut off the Adventurers' trade with the Low countries and the Hansa was thus able to obtain a monopoly of the English cloth export to Antwerp. In retaliation, the Hansa's London privileges were revoked in 1552; briefly restored, they were suspended in 1555. Queen Elizabeth in 1560 made peace with the Hansa; the terms excluded the Hansa from the Antwerp cloth trade and abolished their customs exemptions in London. Thus the Merchant Adventurers finally won their long trade war.

MERCHANT MARINE OF THE UNITED STATES. The United States merchant marine comprises all vessels of the nation engaged in water-borne commerce. However, in general usage, it is considered to include only that portion of our shipping which sails the seas, thus excluding vessels on the Great Lakes and on inland waters. It is distinguished, in addition, from the ships of the navy, which are sometimes known as the naval marine.

The American merchant marine has had, since the earliest days of the country, two primary purposes: (1) to further and increase national foreign trade; (2) to assist in the national defense. Throughout American history it has been an instrument of national policy. While it is pleasant to think of a ship as an instrument of peaceful trade between nation and nation, yet it is a fact that merchant ships have been used repeatedly for military purposes.

Under the Merchant Marine Act of 1936, the United States for the first time instituted a realistic policy concerning the operation and financing of the nation's merchant marine. The United States Maritime Commission was established, and upon it devolved the duties of interpreting the major purposes of the act. (See UNITED STATES—*New Federal Agencies.*)

In 1938 a program of shipbuilding, envisaging the construction of at least 50 ships a year for 10 years, was launched by the commission. These vessels were to replace the slow and obsolete ships which, as of the inception of the commission's program, comprised over 90 per cent of the nation's ocean-going fleet.

The European war which broke out in September 1939 sharply increased the demand for merchant shipping. Under the Neutrality Act United States ships were forbidden to carry trade on two fifths of their accustomed routes. The withdrawal of thousands of vessels of belligerents from international trade, however, together with increases in freight rates in all parts of the world, gave American shipping an opportunity to expand services on neutral trade routes. When the United States entered the war, the armed forces drew on the merchant marine for many of their auxiliary vessels, and throughout the war merchant ships carried the great bulk of men and materials to places where they were needed, thus vindicating the national defense aspect of the American merchant marine policy much sooner than any of the promulgators of the 1936 act had expected.

A huge emergency shipbuilding program was superimposed on the original long-range program, and by the war's end the United States merchant marine contained over 6,000 ships, most of them new. Since the war these ships have had to be put into private operation, and readjustments made to meet changed peacetime requirements for merchant shipping.

The early years of American shipping were ones of peaceful development and aggressive mercantile adventuring.

Colonial Period.—The white man first approached the shores of the newly discovered continent of America in a ship; and for nearly two centuries thereafter the sea and the inland waters were his chief avenues of communication. The whole early history of the development of the United States is closely interwoven with the history of the expansion of its merchant marine.

Long before actual colonization had begun, the daring fishermen of the British Isles, the Dutch lowlands, and the rough coasts of Brittany had crossed the sea in their cockleshell fishing boats to reap the harvest of the Grand Banks—cod and other fish—and had used the forbidding shores of what are now Canada and the New England states as curing stations where they salted down their catch.

The British, restlessly seeking expansion from within their small island territory, were the most daring of these fisherfolk, and it was they who first colonized America's eastern coasts. When King James made a grant to the Plymouth Company in 1606, it was primarily for the purpose of establishing a fishing colony where much of the work of curing the cod-catch could be done by the permanent settlers, rather than by men specially brought over with each vessel to do the task.

The first settlement on the northeastern American coast was known as the Popham colony, on the Kennebec River in Maine. It was here that the nation's merchant marine had its inception, in the fall of 1607, when the colonists laid the keel of the *Virginia.* This was a seagoing pinnace of 30 tons, undecked and propelled with two sails.

and oars if the wind should fail. In this frail craft the colonists fished the Banks, and even made a voyage from the Kennebec River clear across the Atlantic.

Though the Popham colony failed, the tradition for industry, daring and ingeniousness established with the little *Virginia* carried the American colonists ahead until, about 200 years later, they were masters of sail and able to compete with the fleets of the world in foreign trade.

That ships were absolutely necessary to the early colonists is evidenced by the fact that each one of the early settlements produced one or more sailing vessels within a short time after their founding. In 1611 the Jamestown colonists built a 13-ton shallop; in 1614 Adrien Block, of New Amsterdam, built a "yacht"—the first decked vessel constructed in the colonies; and in 1624, only four years after it was first founded, the Plymouth Colony of Pilgrims launched two small shallops to export cod to England. A shallop was a small, open-decked, two-masted vessel usually used for fishing purposes. Other shallops laden with fish sailed down the coast to trade with the Southern colonies and the West Indies. To avoid a profitless empty hold on the return trip, these vessels purchased cargoes that could be disposed of at home—sugar, rum, tobacco, and the like—and before long many of the ships were engaged entirely in carrying miscellaneous cargoes wherever profitable. In other words, they became our first merchant marine.

So urgent became the need for ships that in 1629 the first formal shipyard in America was established on the Mystic River in Massachusetts. The Puritans, settled at Salem, chose that location for the venture because it was well sheltered from the sea storms. On July 1, 1631, the 30-ton bark, *Blessing of the Bay,* was launched from the Mystic shipyards. Another yard, established the same year on Richmond Island off Cape Elizabeth, Me., built America's first ship for "export"—a sailing vessel for English purchase.

By 1635, less than 30 years since the launching of the first ship in colonial America, the British Admiralty announced that there were six American-built and owned ships in regular commerce between the colonies and the mother country. Thus aggressively was the maritime history of the Western Hemisphere originated.

Shipbuilding, in fact, was one of the major industrial pursuits of the colonies until the revolution. The early American colonists faced a vast, wild, and forbidding hinterland. They scratched out small patches of ground on which to raise sufficient food to support themselves, and turned to the luxuriant forests which blanketed the continent for materials with which to build ships for trade. Not for decades did the exploring instinct take the colonists more than a hundred miles or so overland into America's interior; but from the start they treated the Atlantic as their highway, and plunged fearlessly into the forests to provide themselves with the stout timber needed for their ships. Even at that time, English forests were already impoverished, and American ships and shipbuilding materials became one of the country's major exports to England.

While American shipping and shipbuilding were in the period of early growth, the mother country assisted it by laws, passed in 1646 and 1650, limiting trade with the colonies to vessels sailing under the British flag. This meant that American-built ships were for awhile given a practical monopoly (along with British vessels) in colonial trade.

However, as American adventurousness in maritime trade and American industry in shipbuilding continued to increase, Great Britain changed her policy. In 1660 and 1663 navigation laws were passed requiring all major American exports to be transshipped through English ports. The colonists, however, were not men to submit to such tyranny; during the next century they turned to smuggling on a huge scale. They evaded the transshipment laws simply by not paying any attention to them, and by openly importing and exporting goods directly to America. Commerce seemed to feed on the British restrictions; it was as if the Americans were goaded to greater efforts by the highhandedness of the British kings and their representatives.

The story of the American merchant marine for the whole period from 1660 to 1770 is one of increasingly successful colonial shipping, working against an increasingly repressive policy on the part of the mother country. The colonists successfully boycotted British manufactures, and smuggling became not only respectable but patriotic.

As an indication of the health of American commerce, the figures on shipbuilding are illuminating. In one year alone, 1769, the American colonies built and launched 389 sailing vessels. And in 1776, just at the beginning of the Revolution, it was estimated that over one-third of the British ocean-going merchant marine was composed of American-built ships.

Among the major maritime occupations, other than smuggling, which flourished before and after the revolution were deep-sea fishing, whaling, and slave trading. Whaling, about which some of the most thrilling pages of American maritime history were written, started in 1712, and by 1770 Nantucket alone owned 125 whalers, which that year brought in a cargo valued at $358,000. Slaving, too, was enormously profitable; it laid the foundations of some of America's greatest fortunes.

The Revolutionary Period.—Not all was serene and prosperous, however. While a few American merchantmen made over 700 per cent profits on single voyages, the great majority of them were not so fortunate. The British, in the middle of the 18th century, began wreaking havoc on colonial shipping. Up to the American Revolution they had captured over 300 American trading vessels, and had caused such a rise in shipping rates that many foreign commodities were completely beyond the reach of the average American colonist. British raiding of America's "illicit" commerce may be said to have been the basic cause of the Revolution.

The Revolution nearly ruined both British and American shipping. British war vessels and privateers annihilated the American fishing fleets, and either sank or captured more than 1,000 American merchantmen. They succeeded in bringing normal trade between America and Europe to a complete halt for several years. At the same time, American privateers, numbering over 1,600 vessels, together with the 30 ships of the American Navy, captured or sank as many as 3,000 British vessels. Of the 30 naval ships only nine remained at the end of the war, however; and according to most authorities it must be admitted that the British Fleet defeated America at sea in the revolution.

Moreover, though the privateers brought considerable assistance to the beleaguered American forces, the privateer tradition resulted in the growth of piracy after the war. The usual concept of our country's early merchant marine as a fleet of vessels valiantly fighting for freedom is not one entirely upheld by the facts. Smuggling, slaving, and piracy were the major sources of the private incomes of American shippers in those days. There were excellent reasons for this—the British restrictive legislation both before and after the Revolution. But those reasons do not erase the picture of the American merchant marine of the 18th century as a fleet of adventurers.

The first accurate figures on the deep sea tonnage of this nation were obtained in 1789, when 123,893 tons of American shipping were registered. The smallness of this figure resulted from the chaotic conditions at sea immediately following the Revolution. It was not until Congress first met as a body legally authorized to pass laws for the nation as a whole, in the year 1789, that the merchant marine had a chance to grow under normal conditions of national protection. In that year the first Congress required that only United States-built and owned vessels could be registered under the American flag. Another more important law established a discriminating duty of 10 per cent against all goods imported in foreign ships; and further, a discriminating tonnage tax providing a differential nearly 10 times as high on foreign vessels as on American. The result of these discrimination laws was immediately evidenced. From the low tonnage figure of 1789, the merchant fleet of the United States jumped to 411,438 tons in 1792, three years later. In 1789, 76 per cent of the total exports and imports were carried in *foreign* ships; by 1794 the ratio had been startlingly reversed, and American ships were carrying over 88 per cent of American combined imports and exports.

A number of causes, in addition to the country's policy of favoring United States shipping by means of discriminating duties and tonnage taxes, can be found for the relative prosperity of the American merchant marine during the 20 years from 1792 to 1812. Europe was in the throes of the Napoleonic wars much of the time, and both British and French fleets were busily engaged in fighting each other. Despite the ruinous embargoes placed on neutral shipping by both British and French during the 1800's, the United States merchant marine captured a large amount of the commerce of the world at that time.

Moreover, new avenues of trade had been opened. In 1784 *The Empress of China* had made the first trip of any United States vessel to China; and the Chinese market for furs, ginseng, and other commodities brought great profits to American traders. In 1789, 15 American vessels were counted in the Canton roads at one time. To make trade easier with the East, and to tap the enormous wealth in furs of the Far West, John Kendrick and Robert Gray established the first fur post on the west coast, in 1788. Captain Gray made the first round-the-world voyage under the United States flag in the sloop *Columbia,* 1789–90.

Finally, America's own coastal trade brought some prosperity to the nation's shippers. The law of 1789, which established discriminating tonnage taxes, was written in order to give once and for all a practical monopoly in coasting to American ships. This law stated that American vessels in the coasting trade should pay the tonnage tax—$6—only once a year. Foreign vessels had to pay a $50 tonnage tax *every time they entered an American port.* Naturally, few, if any, foreign ships attempted to trade on that basis. In 1808 Congress explicitly forbade foreign vessels in the coasting trade, and it has continued to be a national monopoly.

An indication of the growth of the American merchant marine during this period is found in the increase in the United States tonnage registered for foreign trade: from 411,438 in 1792, to 984,269 in 1810—well over 100 per cent. Similar increases were made in the tonnage of vessels occupied in coastal and inland waters.

From 1812 to the Civil War.—The War of 1812, resulting from the British policy of ruthless sea raiding, impressment of American sailors, and interference with United States trade, caused only a temporary interruption to American shipping, though it was catastrophic while it lasted. More than 500 of the best American merchantmen were withdrawn from normal commerce to become privateers, supplementing the 23 vessels which then comprised the United States Navy. And while these privateers captured or sank well over 1,300 British merchant ships, the British Navy disposed of nearly an equal number of American vessels, causing a shrinkage in American tonnage in foreign trade from the nearly one million tons of 1810 to a little less than 675,000 tons in 1814. American commerce declined from $150,000,000 in 1810 to $20,000,000 in 1814.

But foreign commerce revived soon after the war, and the merchant fleet of the nation grew to considerably larger volume than ever before. The China trade continued to expand; whaling, sealing, and other special fisheries trades brought millions of dollars into American tills; and the development of swift, regularly scheduled packet lines, prophetic of the coming of the clipper, brought more and more international trade into American ships.

One reason for this expansion was the fact that in 1815 Congress passed a law prohibiting foreign vessels from importing any goods to the United States except from the country under whose flag they sailed. The law was used as a weapon with which the United States forced many nations to sign reciprocal trade treaties. Another reason was the general improvement in American ships. Builders had begun to study ship models and rigs, and were able to experiment with reference to the trade needs of the times. Ships became larger, more maneuverable, faster. According to many authorities, the period 1816–1828 was perhaps the most flourishing in all American maritime history. United States ships were everywhere, in every port, competing on equal footing with the vessels of European fleets, and often walking away with much inter-European trade, as well as the bulk of the Far Eastern shipping and nearly 90 per cent of America's own imports and exports.

In 1828, Congress abandoned the preferential duty system, in accordance with the then popular free trade idea. This revocation worked a temporary hardship on American shipping, causing numerous transfers to foreign flags and other defections from the merchant marine. In 1828 American registered tonnage numbered 812,619 tons; by 1830, it had fallen to about 575,000 tons. However, it had returned to the 1828 level by 1834, and from then until the Civil War period

(1861) the American merchant marine under sail grew by leaps and bounds. In that year it was registered at 2,540,000 tons—nearly a fivefold increase in sailing ships alone. The enormous annual growth in immigration from 1825 onward meant profitable passenger lists, and resulted in new, swift, and luxurious types of cargo-passenger combination sailing vessels. Growing industries in the United States also produced more goods for export, and American tastes began to lean toward products of European refinement. All these things helped fill American ships.

It was the great era of the packet line and the clipper. A packet line consisted of a regular service for freight and passengers. Its vessels were common carriers, as opposed to the earlier type of sailing vessel which carried goods only for the owner, or for the owner and a few others who shared in the proceeds of the voyage.

The first American packet line was established between New York and Liverpool in 1816—the Black Ball Line. By 1836 there were 50 sailing vessels in the American packet fleet, running on regular schedules to many European ports, and also to Central American countries. These packets of the sail were relatively small, averaging less than 500 tons, although the *Roscius,* put into service in 1838, was a monster of 1,100 tons. Many of these packets made the Atlantic passage from New York to Liverpool in less than two weeks—magnificent time for ships of the sail.

John W. Griffiths, according to some authorities, was the man who invented the clipper type of merchant vessel. His first ship, the *Rainbow,* went into service in 1841. One of his vessels, the famous *Sea Witch,* ran from Canton to New York via Cape Horn in 77 days—record time for a sailing ship.

The full development of the clipper coincided remarkably with the opening up of the west coast of the United States in the days of the Gold Rush. American shipping during the 1850's might have suffered considerable losses owing to the introduction of steam vessels and of heavily subsidized British lines into the Atlantic trades, had it not been for the enormous trade with California which grew with the exploitation of the west coast gold fields. Right up to the beginning of the Civil War, this trade brought unprecedented prosperity to east coast shippers, and was instrumental in the development by Donald McKay of the most famous clippers—the *Flying Cloud,* for instance, which cut sailing time from New York to San Francisco from 127 days to 89 days.

Other famous American clipper builders were Brown and Bell, Howland and Aspinwall, and William H. Webb, whose *Helena* competed with Griffiths' *Rainbow* for the honor of being the first true clipper. Some of these clippers were capable of 330 miles a day. An average of 15 miles an hour under favorable winds was ordinary. *The Sovereign of the Seas* once sailed 437 miles in 24 hours—a record which many steam or motor vessels of today would find difficult to equal.

The repeal by Great Britain of its navigation laws restricting international trade in 1849 also opened up the Atlantic trades to United States vessels, and the clipper and early United States steamers for several years dominated the Liverpool run. With the end of the Crimean War in 1856, however, the seeds of decay were sown in the American merchant marine. Thousands of tons of British vessels were released to compete in international trade, and as a result, United States shipbuilding, the first of any maritime industry to feel the effects of a foreign trade depression, shrank from nearly 600,000 tons under construction in 1855 to only a little over 200,000 tons in 1860. The Civil War resulted in a complete stoppage of United States shipbuilding, and practically strangled the American merchant marine.

There are several important reasons for this decline, in addition to such incidental setbacks as those in the wake of the Crimean War, the collapse of the gold boom in California, and the Civil War. For one thing, the immense wealth of the American continent was being opened up by the great westward expansion of the mid-19th century. Railroads were absorbing nearly all American capital; discovery and exploitation of American natural resources were luring American men from the sea of their heritage, inland to a new kind of life. The immensities of the American continent offered full scope for the expanding energies of the American people, and interest in the merchant marine in international trade sank very gravely as a result.

The development of steam navigation, and the adoption by European nations of consistent policies of subsidization of their merchant marines, were other important reasons for the shrinkage of American shipping in foreign trade.

The Advent of Steam.—In 1781 the Marquis de Jouffroy ran the world's first workable steamboat down the River Saône, in France. In the 1780's John Fitch of Philadelphia experimented with steam, and one of his vessels was in use as a packet between Trenton and Philadelphia in 1790. William Symington, a Scotsman, further developed and improved the steam vessel; his tug, the *Charlotte Dundas,* was in successful operation in English waters by 1802. Robert Fulton's *Clermont,* first launched in 1807, was an adaptation of Symington's design for use on United States inland waters. All of these early steamboats were operated by paddle wheels, though John Fitch did experiment with screw propulsion as early as 1787.

Though the first steam-and-sail voyage across the Atlantic was made by the American *Savannah* in 1819, using wood for fuel, American steamship development was limited predominantly to the design of vessels useful for service on inland waters. It was not until the 1840's that the United States began to think in terms of regular transatlantic voyages for steam vessels, and then the subject arose only because of a new kind of competition which the British were bringing into effect.

The famous *Great Western* was the first British steamer to enter the regular transatlantic service; her first trip was made in 1837. However, serious competition with American sail packets began in 1840, when the first Cunard liner crossed the Atlantic, subsidized with a British mail contract of £80,000 a year. The United Kingdom also subsidized a steamship line to the West Indies in that same year. Though American sailing vessels for a while kept their advantage in freighting and in the Orient runs, the new, fast, regular British steamers began to eat into the American trade for passengers and fast freight.

As a result, Congress passed its first maritime subsidy legislation in 1845, appropriating $400,000 annually for the Ocean Steam Navigation

Company, New York to Southampton and Bremen, and further amounts to assist in the construction of steamers for the Liverpool run. The latter vessels were to be owned and operated by E. K. Collins, one of the first of the great steamship moguls of America. His four wooden sidewheel steamships competed effectively with Cunard for several years during the 1850's, until Congress in 1858 withdrew the subsidies it had granted. Two other lines, the Sloo and the Pacific Mail, for South America and Pacific runs, both received subsidies. Because of the enormous profits made from the gold rush, they were able to make money. Collins, however, was constantly in financial difficulties, not only because of mismanagement, but also because of insufficient competitive subsidies.

When American policy turned against subsidies in 1858, the steamship lines were all, with one or two exceptions, forced to suspend operation. The percentage of the value of United States foreign trade carried in American ships dropped from 73.7 per cent in 1858 to 25 per cent in 1866. Until World War II our ships never regained as much as 40 per cent of the total import and export carriage of the United States trade.

The Civil War to World War I.—The Civil War did not, of course, destroy the United States merchant marine, but it did nothing to retard the self-destructive tendencies which were already evident within it. Anglo-Confederate cruisers harried northern merchantmen, causing insurance rates to skyrocket, and resulting in the transfer of over one third of the total registered tonnage of the Union to foreign flags. Shipyards were abandoned; many vessels were sunk or captured; and many more merchantmen were taken from their accustomed trade routes and put into blockade duty around the ports of the Southern states. All this meant severe dislocation to the nation's shipping and its foreign trade as well.

After the end of the Civil War, American shipping in foreign trade continued to decrease steadily. There are many reasons for this, among the most important of which are the following. In the first place, United States shipbuilders and shipowners proved unusually reluctant to adopt the most modern and advanced type of ship. The iron ship had its first success in Great Britain, whereas Americans continued to build wooden vessels. This was owing to the fact that Britain's iron technology developed at a swifter rate than America's, since a chronic lumber shortage in England made the use of iron a necessity. The United States, on the other hand, had enormous reserves of standing timber, and American shipbuilders preferred to use that material rather than rely on the lagging and inefficient American iron founders for shipbuilding materials.

Moreover, although an American, John Ericsson, is said to have been the first to perfect a practical screw method of vessel propulsion, here also the United States lagged far behind the British in adopting that method of propelling its steam vessels. Ancient American sidewheelers were ploughing across the Atlantic long years after the British, with the aid of liberal subsidies, had replaced their older wooden vessels with relatively swift and safe iron ships propelled by the screw.

In the second place, the pressure of the Western agricultural states against ship subsidies resulted in a complete absence of coherent subsidy legislation during the whole period. American ships found it impossible to compete with the large and regular mail subsidies paid to Cunard by the British government. For a brief period, 1865–1875, Congress subsidized a few lines to Latin America and the Orient; but as a result of scandals connected with payments to the Pacific Mail Line, all these subsidies were withdrawn. No payments were paid to steamship companies in competition with Great Britain on the important Atlantic run from New York to England.

A third reason, previously mentioned, continued in effect with unabated force during the whole of the 19th century: and that is, the internal expansion of the nation, the development of American industry, the leap into boisterous manhood of an inventive people in a nearly self-sufficient land. American economy did not need a national merchant marine in those days.

Finally, a fourth reason for the continued slump in the registered fleet in foreign trade of the United States was, of course, the coincidental profitable growth in the coastwise and intercoastal monopoly of American shipping. While United States vessels in foreign trade decreased in tonnage from over one and a half million tons in 1870 to under 800,000 tons in 1910, the tonnage engaged in the coastal, inland, and Great Lakes trades rose from 2,729,700 tons in 1870 to 6,716,200 tons in 1910, over two and one-half times.

Nevertheless, many forces were at work to bring the nation back into the international shipping picture. Shipbuilders and ship operators both desired a larger portion of the American carrying trade. The danger of monopolies abroad constantly suggested the possibility of prohibitive freight rates imposed by closely held European shipping combines. The need for a merchant marine in the organization of national defense was also often stressed by thoughtful people.

As a result, in 1891, a conservative mail subsidy law was entered on the nation's books. A total of $29,630,000 was spent during the life of the act, more than half of this sum going to ship lines operating in the transatlantic trades. Nevertheless, total expenditures were less than one half those of Canada, and one sixth those of England during this period.

It was hoped by the promoters of the law that the subsidies would encourage the building of new ships for the mail lines. However, the advent of the Spanish American War indicated that those hopes had not been translated into fact, largely because of insufficient operating bounties and the entire absence of financial aid for ship construction. During the war period, 1898–1899, Congress had to permit the temporary registry of 42,700 tons of foreign vessels, in order to cope with the problem of transporting United States troops and supplies to Cuba, the Philippines, and elsewhere. The army and navy bought another 94,000 tons of foreign shipping to care for their requirements. The actual tonnage registered for foreign trade *decreased* from 844,954 in 1896 (both sail and steam) to 826,694 in 1900.

More generous operating subsidies and the institution of a policy of ship construction subsidies were constantly urged in Congress, but with no success up to the year 1916. The agrar-

ian states, continuing to fear a rise in shipping rates, succeeded in defeating all attempts at establishing national protection for American registered shipping.

The only additional assistance to United States shipping which the government was able to bring forward between the years 1898–1916, was the extension of the coastal monopoly to include Hawaii and Puerto Rico, and trade via the Panama Canal from one coast to another.

In the spring of 1915 the Nelson Act, often miscalled the LaFollette Act, was signed by President Wilson. This law provided a "new deal" for American seamen. It entirely abolished imprisonment for desertion. It set up requirements for better working conditions, manning scales, and food. Tests by the Department of Commerce were required before a man could receive his able seaman's certificate; and 75 per cent of the crew had to be able to understand the language of their superior officers, thus virtually eliminating low-paid Chinese crews on American vessels.

Also, in 1914, there was a congressional investigation of liner shipping, and of the combinations in support of fixed rates into which various lines entered. These combinations are called *conferences*. The investigation discovered no discrimination against American ships, but did reveal certain unfair practices by the conferences, which were finally outlawed in 1916. These practices included deferred rebates, preference contracts with large shippers, and "fighting ships." The fighting ship was a vessel assigned by the conference to undercut the rates of nonconference lines which were, in turn, undercutting the conference rates. With the elimination of the discriminations above outlined, the conference system of interline self-regulation has proved a sound way of avoiding cutthroat competition and a constantly bankrupt merchant marine.

World War I and Shipping.—The outbreak of World War I in August 1914, provided a major turning point in the history of the American merchant marine. In 1912 about one million tons of ocean shipping, owned and controlled by American capital, were operated under foreign flags. When the war began, a large number of these vessels returned to American documentation, in order to escape capture by the warships of belligerent nations. As freight rates began to increase and more and more ships belonging to belligerents were immobilized by the war, hundreds of thousands of tons of American coastwise shipping transferred from domestic to overseas routes to take advantage of the wartime prosperity in foreign trade.

The proportion of United States imports and exports carried in American vessels jumped from 9.7 per cent in 1914 to 16.3 per cent in 1916. High freight rates caused such a demand for shipping that buyers gladly paid up to $300 a ton for ships which, before the war, could have been bought for $60 a ton.

American shipbuilding did not noticeably increase. While there was a growth of approximately 100,000 tons in 1916, 120 *fewer* vessels were built than in 1915.

The enormous increase in freight rates brought about a congressional investigation in 1914, which discovered rate increases in cotton shipments from New Orleans to Liverpool, to take an example, of from $2.50 per bale before the war to $50.00 per bale in 1914. In 1916 a bill was passed to regulate rates.

The Shipping Board Act, as it was called, authorized the establishment of a United States Shipping Board, whose function was to supervise ocean freight rates. Deferred rebates, preference contracts, and fighting ships were all forbidden. The board was given power to disapprove, cancel, or modify any conference agreement it found to be discriminatory or unfair.

By that time the nation was on the verge of a declaration of war with Germany. The provision for government construction of ships became the most important section of the act, and one of the first major steps of the newly created board was to set up (April 16, 1917) the Emergency Fleet Corporation, to carry out the herculean task of building a "bridge to France." The funds earmarked for ship construction were increased in June 1917 from the $50,000,000 provided in the act, to $750,000,000, and before the end of the war, to a total of $2,884,000,000. This sum was used for ship and shipyard construction alone. Other funds for the purchase and operation of ships already afloat brought the total spent on an emergency fleet to over $3,000,000,000 by the time the program was completed.

Less than one sixth of the Fleet Corporation's ship construction program was completed by the end of the war; and meanwhile the transport problems of the army and navy had to be solved. The government borrowed 1,200,000 tons of cargo shipping from Great Britain in September 1918. More than one half of the United States troops sent abroad during the war period were carried in English, French, and other allied vessels.

Early in 1917 the nation had 61 shipyards with a total of 225 ways. On Nov. 11, 1918, there were 341 shipyards with 1,284 launching ways in the United States. The number of workmen in the shipyards had increased from 45,000 to 380,000. During its whole period of existence, the corporation built 2,318 ships, totaling over 14,000,000 dead-weight tons. Some 5,000,000 tons of ships, over one third of the total, were actually started after the armistice, the last vessel built not being delivered until May 1922. Many of the ships were of poor quality, low speed, and short operating life. The corporation paid from $150 to $200 a dead-weight ton, whereas, before the war, good steel cargo steamers were built in the United States for about $65 a ton.

Perhaps the most famous of the wartime vessel types was the Hog Island freighter, with a cargo capacity of 4,963 gross tons and speed of about 11 knots. Built on a mass-production basis at the shipyard at Hog Island near Philadelphia, it became a distinctive part of the American merchant marine during the next 20 years.

During the war, the shipping industry operated completely as an arm of the United States government. At the end of hostilities, the board found itself responsible for a huge, government-owned fleet which, under the law, it was obligated to transfer to private owners or operators within five years after the end of the war. The Merchant Marine Act of 1920 was passed by Congress to enable a new Shipping Board to dispose of the vessels, and to assist private operators, under charter or as managing agents, in running them.

The act also set up a construction loan fund of up to $25,000,000 for loans to private companies to build new ships. The postmaster gen-

eral was given the authority to make contracts for the carriage of mail on Shipping Board trade routes without asking for competitive bids. During the period from 1924, when the first subsidy was paid under the act, to 1929, when the Merchant Marine Act of 1928 went into effect, only $4,801,953 was paid out in mail subsidies, and only six lines benefited.

By June 30, 1928, 1,164 cargo and other types of vessels had been sold at an average price of about $18 a ton to operators who would agree to make a stated number of sailings in a stated trade with the ships they purchased. The Shipping Board itself operated vessels on several lines, usually at a loss. Finally, many of the remaining vessels were temporarily retired from service.

The postwar world depression affected American as well as foreign shipping. At the same time that there were surpluses in ocean-going tonnage in every one of the major maritime nations, foreign trade dropped, and never, during the prosperous 1920's, rose to a point where the world's shipping was able to run at a profit on cargoes alone. Although the percentage of American foreign trade carried in American vessels rose from an average of 10.6 per cent in 1911–1915, to an average of 35 per cent in 1921–1930, the newer European postwar merchant fleets, subsidized both as to construction and as to operation by their increasingly nationalistic countries, undercut the relatively unsubsidized American fleet until it became obvious that most American shippers would be unable to continue in business without further assistance.

In 1928, an effort was made to put America back into competition with the merchant fleets of other nations through a new Merchant Marine Act which authorized much heavier mail subsidies. Construction of new vessels in American shipyards was required of recipients of the subsidies, and as a result, there began the first new ship construction since World War I. Forty-two vessels were built under the act, between 1928 and 1936, totaling less than half a million tons. Forty-three mail subsidy contracts were let, involving an average annual expenditure of a little less than $20,000,000.

Even these sums of money proved insufficient to put the American merchant marine on its feet. Many of the recipients were not operating efficiently enough, or under the right type of regulations, to forward economical and successful shipping. Moreover, the continuing growth of foreign trade fleets resulted in a world fleet much superior in size, speed, and efficiency to the American vessels.

The higher costs of American operation of shipping were due to three factors: (1) much higher overhead and carrying charges on an average American vessel, unsubsidized as to construction and unassisted either directly or indirectly in operation; (2) increased costs in upkeep due to higher standards of subsistence and safety; (3) higher costs of labor on American vessels.

The first attempts to improve the situation took the form of laws designated to improve safety and working conditions, the first such laws passed since 1915. The Bureau of Marine Inspection and Navigation was reorganized and its authority increased. Marine casualty boards were established to deal with questions of negligence leading to marine disasters on the part of marine personnel.

Finally, the Roosevelt administration asked Congress in 1935 to give the United States a realistic policy for its ocean-going merchant marine, and the right to support that merchant marine with direct and easily controllable subsidies.

The Merchant Marine Act of 1936 finally was passed and signed. One of the first actions of Mr. Roosevelt as president had been to put the old Shipping Board into the Department of Commerce as the United States Shipping Board Bureau. The new act abolished the bureau entirely, as well as the Merchant Fleet Corporation which had succeeded the old Emergency Fleet Corporation. It also established the United States Maritime Commission to administer the act, and authorized it to cancel the ocean mail contracts executed under the 1928 act. These contracts were cancelled by June 30, 1947, and claims totaling over $73,000,000 were settled at a net cost to the government of approximately $750,000.

The chief feature of the legislation, however, was the frank power of subsidy which it granted the commission. The new subsidies were intended to give private industry the difference in cost between both construction and operation in the United States and in a foreign nation. The act authorized the commission to establish rules and regulations which would assure efficient use of its funds; to provide for the determination of essential trade routes; to create minimum wage and manning scales and working conditions; to create a training program for American seamen; and to set up a construction program for the replacement of the country's obsolescent shipping.

The new commission made an extensive survey of the merchant marine as it then existed. It discovered in this survey that over 90 per cent of the existing American merchant fleet in foreign trade would be over age by 1942.

The commission immediately embarked on a large-scale construction program, which envisaged the building of 50 ships a year for 10 years. By Nov. 1, 1940, contracts had been let for 179 cargo, cargo-and-passenger combination, and tanker vessels. The vessels were the most modern, most efficient, and most economical afloat. Included in the program was the largest passenger liner ever built in an American yard, the *America,* which was put into service in the summer of 1940.

Subsidies on ship construction under the commission's program amounted to between 30 per cent and 45 per cent of the actual cost of construction in American yards. Operating subsidy outlays in 1937, 1938, and 1939 averaged approximately $13,000,000 per year.

New safety and maritime labor legislation adopted in 1935 and 1936 plus unusually high constructive standards have made the commission's ships the safest in the world.

The American Merchant Marine in World War II.—The emergency shipbuilding program instituted at the outbreak of World War II produced 185 new ships within two years, but when the United States was forced into the war, it was evident that this program must be expanded many times. All resources were mobilized for another great shipbuilding effort. The basis of the new program was the 10,000-ton 11-knot Liberty ship, a standard cargo vessel modeled on an old British type, that could be built quickly and did not require the complicated propulsion machinery that was in great demand for naval vessels. The race between the German submarines and the Amer-

ican shipyards was won by the yards within a year and a half after our entry into the war. The 40 shipyards available at the start of the war increased to nearly 80, employing 700,000 workers, who turned out over 5,500 ocean-going vessels, an average of one vessel every 6 hours night and day, for 4 years.

A new government agency, the War Shipping Administration (WSA), was formed in February 1942 to take over the task of manning and directing the operation of these vessels, while the Maritime Commission continued to administer the shipbuilding program. The WSA operated in close cooperation with the Maritime Commission, many of whose officials also served in the new agency, and with the armed services and government departments of both the United States and other Allied nations. The War Shipping Administration recruited 100,000 former seamen and trained over 200,000 men to man the ships, and directed the transportation overseas of millions of soldiers, their weapons and supplies, and four fifths of the cargo required for the entire United Nations war effort. In addition, ships under WSA control carried essential supplies for the United States civilian economy and the imports needed to sustain war production. Many vessels were turned over to the army and navy to serve as hospital ships, repair vessels, oil and cargo carriers, and for other special uses.

Many merchant vessels also took an active part in the fighting. In addition to landing troops and cargo under fire, a number of merchant ships sank enemy submarines and shot down enemy planes. Some old damaged vessels were sunk off Normandy Beach to serve as breakwaters and to support the piers used in landing supplies for the European invasion. About 700 ships were sunk and 5,600 seamen lost, but merchant ships kept on carrying men and goods to and from battlefronts all over the world until the war was finally won.

Postwar Reconversion.—While war plants closed down and the armed forces were demobilizing, the merchant marine was busier than ever. Seven million men had to be brought back from overseas, together with many war brides and children. To the devastated nations of Europe and Asia, cargo vessels carried millions of tons of grain, coal, flour, and other relief supplies.

In addition to the government-built and government-owned ships which had been operated by the government through private agents, about 900 privately owned merchant vessels had been requisitioned by the government for war service. These vessels had to be returned to their owners and compensation paid for their use. Where vessels had been lost, insurance had to be paid or another vessel made available as a replacement.

Since private ownership of merchant vessels insofar as practicable is the general policy of the United States, when the war emergency was over, the Maritime Commission was directed by Congress in the Merchant Ship Sales Act of 1946 to sell as many of its war-built vessels as possible to private operators. Up to September 30, 1949, 1,831 vessels had been sold, of which 1,113 had gone to foreign nations to replenish war-depleted merchant fleets, and 718 of the best types had been sold to United States operators. After March 1, 1948, government-owned vessels could no longer be sold to foreign buyers. There were 2,095 vessels laid up in reserve fleets at seven permanent and two temporary sites. Some of these laid-up vessels, carefully preserved, will be kept as a reserve for emergencies. Until June 30, 1950, when the Commission's sales authority was due to expire, others might be sold to American operators, or, if they were too badly damaged for further use, they might be scrapped.

On September 1, 1946, the War Shipping Administration was dissolved and its remaining functions turned over to the United States Maritime Commission.

There was not enough privately owned tonnage available to meet the heavy postwar demands for relief and rehabilitation cargoes. Pending completion of the ship sales program and restoration of normal shipping conditions, Congress sought to provide sufficient tonnage under the United States flag to meet these needs by authorizing the Maritime Commission to charter war-built government-owned ships to private American operators. This authority was also due to expire on June 30, 1950. As of September 30, 1949, there were 182 government-owned ships in operation. During and immediately following the war, the Commission and the War Shipping Administration had operated vessels through general agents. Such active general agency operation had ceased by the fall of 1949. Privately owned active United States ships of 1,000 gross tons or over (exclusive of those on the Great Lakes and inland waterways) totaled 1,032 of 12,452,000 dead-weight tons, making an active fleet of about 1,214 vessels in the United States merchant marine at that time.

The vessels built during the war were for the most part emergency types like the 2,710 Libertys and the 531 slightly larger and faster Victorys. These ships were not designed for competitive peacetime operation. The original 500-ship long-range program had been finished years ahead of time, and most of these C-type ships and large tankers were quickly sold to American operators after the war. A few vessels designed as troop carriers could be reconverted for use as passenger vessels. There were 127 passenger or passenger-cargo vessels with a total passenger capacity of 38,357 in active operation before the war. All were taken over by the army or navy for war service, and 52 were lost. Others were too badly damaged or too old to be worth reconverting. The number which, like the S.S. *America,* were reconverted and returned to service, make up a passenger fleet only about one third the size of that operating before the war. High postwar shipbulding costs, and uncertain prospects for United States passenger ships in competition with airplanes and with foreign liners, together with steel shortages and the difficulty of determining fair subsidy rates, delayed the start on a liner replacement program.

Increased costs for new ship construction, plus the large number of war-built ships available for sale at comparatively low prices brought about a sharp slump in the American shipbuilding industry. War-built emergency yards were closed down. Even long-established yards closed or turned to other types of work, while many skilled workmen left the industry. In 1947 only 26 cargo ships, 2 combination passenger-cargo liners, and 2 tankers were built. The president and other high officials pointed out the serious implications of this curtailment of shipbuilding capacity to the maintenance of an up-to-date merchant marine and to the national defense.

The United States Maritime Commission shortly after the war had worked out a long-range program indicating the need for a minimum of 1,044 vessels of 11,400,000 dead-weight tons to serve 31 trade routes determined to be essential to the United States economy and defense. The plan proposed the building of about 144 new vessels in the next 10 years, of which 58 would be combination passenger-cargo vessels and 86 freighters of specialized types not available from the war-built fleet. In addition a number of high-speed tankers would have to be built to meet constantly increasing requirements for oil transport. A replacement program to keep the fleet up-to-date and prevent its becoming obsolescent all at the same time was also proposed.

In 1947 President Truman appointed 4 leading industrialists and a high ranking naval officer to serve as an Advisory Committee on the merchant marine. After an extensive study of the needs of the merchant fleet, this committee issued a report in November 1947 proposing a shipbuilding program of 46 passenger vessels in the next four years, together with a number of high-speed dry cargo ships and tankers. Early in 1948 a committee of Cabinet members recommended through the secretary of the navy that Congress increase the merchant shipbuilding appropriations for the fiscal year 1949 to $100,000,000, of which $90,000,000 would be for new construction. It was pointed out that 50 additional passenger vessels would be needed to furnish troop carrying capacity estimated as minimum in case of war, plus 170 tankers within the next four years.

In response to these requests, Congress made available about $178,000,000 in contract authority for ship construction during the 1949 fiscal year, and the Maritime Commission requested ship operators to determine their shipbuilding needs and to place contracts as soon as possible. Up to November 1, 1949, contracts had been placed by the Maritime Commission for three round-the-world combination passenger-cargo vessels of 13,000 gross tons each, two passenger vessels of 21,000 gross tons each for Mediterranean service, and one 48,000 gross-ton transatlantic "superliner," with construction subsidies to be paid by the government in additon to payments for special national defense features. Bids were also received on a vessel for South American service and two passenger-trailer ships for domestic Pacific Coast service, the latter to be built without subsidy but with mortgage aid. Several other operators had expressed an interest in ordering new passenger vessels, and for the first time since the war's end there was a brighter prospect for the rehabilitation of the depleted United States passenger fleet.

The Commission had also contracted on its own account for a prototype cargo vessel, designed to serve as a replacement for vessels of the peacetime fleet which had become obsolete and also as a model for mass building in case of emergency.

At the war's end the United States merchant marine was the only important fleet which was much larger than before the war. These ships were called on to carry the major part of the relief cargoes going abroad. The profitable operating conditions during the period just before and after the war helped to reduce the cost to the government of ship operating subsidies. The Merchant Marine Act of 1936 provides for the return of one-half the profits earned by a subsidized operator in excess of 10 per cent of the capital necessarily employed in his business, up to the full extent of the subsidy received. Under this provision, the 10 shipping companies whose first 10-year subsidy contract periods ended on or before September 30, 1948, will return about two-thirds of the subsidy paid them.

Gradually, however, as other countries built up their fleets by new construction or by buying surplus United States ships, foreign competition for available cargoes increased and demand for United States shipping fell off. The need of other nations for United States dollars made them eager to use their own ships, both to earn and to save dollar payments. The share of United States trade carried by American ships dropped from nearly 70 per cent shortly after the war to less than 50 per cent, fiscal year 1949.

In setting up the Economic Cooperation Administration, however, Congress stipulated that half of the relief and reconstruction cargo originating in the United States must be carried in United States ships. This made it possible for American flag ships to continue to share in the available trade. Nevertheless, decreases in bulk shipments of coal and continued lack of imports from other countries meant a gradual decline in United States shipping and a return to the government of many of the ships chartered by private operators. Increases in wages of American seamen and in other operating costs such as food, insurance, repairs, etc., have made it more difficult for United States operators to meet lower cost foreign competition. Since subsidy payments are based on the differences between United States and foreign costs, the devaluation of their currencies by many leading maritime nations late in 1949 increased this differential, in some cases beyond the limitation of 50 per cent of the United States cost set by the Merchant Marine Act of 1936 for construction-differential subsidies. For this reason President Truman in the fall of 1949 directed the Maritime Commission to study the situation and present its views to Congress in 1950 for possible modification of existing legislation.

Domestic shipping, which furnished a large number of ships for war service, has not been able to regain its prewar position. Before the war coastwise and intercoastal dry cargo carriers numbered 400 of 2,700,000 dead-weight tons. On September 30, 1949, there were about 131 of 1,189,000 dead-weight tons, much of it in bulk or coal trades. Although protected from the foreign competition which oceangoing ships must meet, domestic lines are handicapped by the depressed rates of competing land carriers and their own sharply increased postwar costs. Until June 30, 1947, the United States Maritime Commission had operated some essential domestic services through general agents, but on that date it withdrew from all remaining services of this type. However, the government charters vessels to private operators in domestic trades at lower minimum rates than those obtained from operators in foreign trades. Although an overall review of rail-water rates by the Interstate Commerce Commission has not been made, several increases in rail rates have given some relief to water carriers who could raise their rates correspondingly.

Future prospects for shipping prosperity depend on a fair adjustment of rates between domestic land and water carriers, the revival of

healthy international trade, and on continued support by the American people of an active and efficient American merchant marine for purposes of national economy and defense.

PHILIP B. FLEMING,
Major General USA, Chairman, United States Maritime Commission.

MERCHANT OF VENICE, The. 'The Merchant of Venice,' entered in the stationer's register in 1598, and published in quarto form in 1600, was written about 1594 or 1595. Several stories that had long had currency in the world—notably the story of the caskets as a device for the choice of suitors by a wealthy heiress, and the bond story of the rich Jew and his debtor — are happily blended in this play, and thereto are added the story of the rings, the romantic minor plot of Lorenzo and Jessica, and the comic character of Launcelot Gobbo. Shakespeare never constructed a better plot, or one better calculated to win popular approval. It meets every demand of stage-management. Although the two main incidents—the choice of the caskets and the pound of flesh—are almost childishly absurd, they are made to seem probable and even natural by the romantic atmosphere in which the characters move. Whether walking the streets of Venice or watching the moonlight sleep sweetly upon the banks of fair Belmont we breathe the air of the Renaissance in Italy. All the characters fit in perfectly with this background except Shylock. Unquestionably to an Elizabethan audience the impression made by him was partly humorous and not at all typical. With his huge nose and the red wig of the traditional Judas he was fair game, not only for the characters in the play, but for those in the pit. His practice of usury and his Jewish qualities rendered him the legitimate object of hatred and ridicule—his passionate words of rage only increased the laughter of an Elizabethan audience. While Shakespeare gave sufficient ground for this interpretation of the character, he has so humanized him as to produce a different effect on a modern audience. His famous words, «Hath not a Jew eyes, etc.,» are an instinctive protest against race hatred and in favor of social sympathy. Whatever may be doubtful in the interpretation of Shylock, there is none in the interpretation of Portia. There is no better illustration of the power with which Shakespeare transformed his material than in the change of Portia from «a piratical and widowed siren, who persuades merchants to stake their all against her hand that they will possess her person, and who then drugs them at supper» into one of the most charming characters of all times. Her beauty of person, brilliancy of intellect, nobility of soul, and gift of poetical expression, all combine to produce an effect not surpassed by any other creation of the dramatist. She is the bond of union between the casket story and the pound of flesh story, and all the other characters group themselves naturally about her. The concluding scene of the play at Belmont, after the excitement of the trial scene and the disappearance of the sinister character Shylock, is one of the supreme passages of poetry in the language—almost magical in its beauty of background and expression.

EDWIN MIMS.

MERCHANT VESSELS, Neutral. At the Washington Disarmament Conference of 1921–22, Elihu Root remarked, as to the term *merchant vessel*, that it «could not be made clearer by the use of definitions which would only serve to weaken and confuse it.» In general, the term refers to any vessel not owned or operated by the government of any state, though even this distinction is clouded by the recent practice in which governments have engaged, that of owning or operating vessels for commercial purposes. In time of peace, such a vessel encounters conflicts of jurisdiction as it moves from one country to another. Upon the high seas, it is subject to no interference or control by any state other than its own; within the territorial waters of a foreign state, it is, for the most part, subject to the jurisdiction of that state. In time of war, the merchant vessel encounters much more difficult and dangerous problems. If it belongs to the enemy, it is subject to capture, or even to destruction. If it belongs to a neutral, it is subject to the international law of neutrality.

Nationality.—A neutral merchant vessel, according to the code prepared by the Research in International Law (see bibliography below) «is a merchant vessel entitled to fly the flag of a neutral state.» The flag is presumptive evidence of its neutral character; this presumption is open to challenge, because it has long been an accepted *ruse de guerre* for a belligerent vessel to carry a neutral flag. The ship must be legally registered with some state, and one state only, to be entitled to carry its flag. The purpose of such registration, said the United States Supreme Court in the case of the *Mohawk* (3 Wall. 571, 1865), «is to declare the nationality of a vessel engaged in trade with foreign nations and to enable her to assert that nationality wherever found.»

Transfer.—On account of the liability of enemy merchant vessels to capture, their owners have frequently sought to transfer them to neutral registry at the outbreak of a war, or when war was imminent. Whether such transfers are legal and entitle the transferred vessel to the immunities of a neutral, are questions which have been much debated. British and American practice during the 19th century admitted the validity of transfers made during, or in contemplation of, war, provided they were bona fide, that is, if the transfer was a fully perfected transaction, in which the purchase price had passed from the purchaser to the former owner, the ship being actually delivered and duly registered in accordance with the registry laws of the state whose flag it was to fly, the former owner reserving no interests or title in the vessel so transferred. Consult the cases of the *Benito Estenger*, 176 U. S. 568 (1899); the *Ariel*, Moore's *Privy Council Cases* IX, 128 (1857); the *Roelfina, American Journal of International Law*, Vol. 16, p. 136 (1922). During the American Civil War, large numbers of vessels under American registry were transferred to neutral flags in order to avoid capture by Confederate cruisers. The French and Russian rules, however, denied the legality of all such transfer made after the outbreak of war. An

attempt was made at the London Naval Conference in 1908 to harmonize the conflicting views, and a draft treaty was actually adopted. This Declaration of London, however, was never ratified, and its rules cannot be regarded as binding upon belligerents. During the World War (1914–18), the question was raised in the case of the *Dacia,* a Hamburg-American liner which, while lying in an American port, was purchased by an American citizen and given American registry. On a subsequent trip it was captured by a French warship and condemned by a French court. A British court, following British precedents, would probably have released the vessel; it was doubtless arranged, for this reason, that the capture should be made by a French cruiser. In view of the treatment which neutral merchant vessels received during the European war which began in 1939, the transfer of vessels to neutral registry offers little advantage.

Neutral Character.—A neutral merchant vessel, once its neutral nationality is clear, may lose some of its neutral rights through its behavior. Many cases and statutes offer justification for capture of a neutral merchant vessel which is carrying enemy military persons, conveying dispatches or transmitting military intelligence, accepting charter from a belligerent, piloting a warship, or providing other such services. Thus, in the case of the *Orozembo* (6 C. Rob. 430, 1807), an American vessel was condemned by a British prize court for carrying three enemy military persons and two civil officials to an enemy colony. In various cases it has been held that the master's ignorance of the fact that dispatches were being carried in his vessel, or even that he acted under compulsion by the enemy, afforded him no excuse. It now seems to be the majority opinion that a neutral vessel sailing under enemy convoy is subject to condemnation; indeed, during the World War and the European war which began in 1939, German warships sank such vessels without warning and without safety for the crews. In the case of neutral vessels participating in hostilities, as by fighting, bringing supplies to warships, transporting troops, transmitting intelligence by radio, etc., the penalty is more severe than condemnation; such vessels may be treated as enemy warships and sunk at once. Unrestricted submarine and air attacks on neutral vessels raise the question whether they should be permitted to arm themselves; if they do so, they would probably be treated as enemy warships. Congress was unwilling to accept President Wilson's recommendation that United States neutral vessels should be armed; the current Neutrality Act forbids arming them for more than internal discipline. As war is now waged, such questions are of no more than academic interest; any neutral vessel is in danger.

Neutral Risks.—According to the law of neutrality, neutral merchant vessels are entitled to navigate the high seas in time of war as in time of peace, subject to certain restrictions and risks imposed for the benefit of the belligerent. If the vessel is carrying contraband of war to an enemy, or running a blockade, it is subject to capture, and it or its cargo or both may be confiscated, if lawfully condemned by a prize court. (See CONTRABAND; BLOCKADE; PRIZE COURTS AND PRIZE JURISDICTION.) For the purpose of ascertaining whether a vessel is carrying contraband or running a blockade, a belligerent warship may order a neutral vessel to stop anywhere upon the high seas, and may there visit and search it in order to ascertain its true character. If such inspection reveals enough evidence, the ship may be ordered into a port of the belligerent, and there held until its fate is decided by a prize court, in accordance with the rules of international law. (See RIGHT OF SEARCH.) In recent wars, however, neutral vessels have been ordered into port, even by radio, for visit and search at the convenience of the belligerent, and at great delay and cost to the vessels themselves. This practice was protested by the United States during the World War of 1914–18, but without success; it is now a regular practice. Indeed, during the World War, a system of «navicerts» was introduced by England, which in the European war that began in 1939, came into regular use. Under this system a neutral vessel is inspected at its port of departure by a British official, and, if no objection can be found, it is given a certificate which, in general, though not absolutely, relieves it of visit and search en route.

Further invasion of the right of neutral vessels to use the high seas is found in the announcement by belligerents of war zones. It was formerly held that a belligerent could not declare a zone of the seas from which neutrals could be excluded; modern warfare disregards this principle. A belligerent now sows mines within a declared area, or sinks neutral shipping in this area (or anywhere else) by submarines or bombs from above. The fact that the neutral vessel has a legal right to proceed in these waters is of little value to it when it may be sunk without warning. Neutral states are entitled to protest against such injury; such protests are ineffective unless backed by force. The United States, which had defended its neutral rights for a century and a half, announced that it would not defend those rights, in its neutrality legislation, first passed in 1935. Under this statute, the neutral United States itself declares «combat zones» into which American vessels may not proceed. It should be noted that this is domestic law, and does not change international law.

Destruction of Vessels.—The above statements lead into the broader question of the right of a belligerent to sink a vessel without warning or adjudication, and without assuring the safety of persons on board. International law has always maintained that the lives of those on board merchant vessels must be protected, and therefore that the ship must not be destroyed, but must be taken into port. In the Russo-Japanese War, a Russian cruiser sunk the *Knight Commander,* a British merchant vessel, on the ground that lack of fuel and of men for a prize crew made it impossible to take the captured vessel into a Russian port. England indignantly protested this as a «very serious breach of international law»; but seven other neutral merchantmen were destroyed by the Russians during this war. The problem was much discussed at the Second Hague Conference, but no agreement was reached. At the London Naval Conference of 1908–09, the general principle was affirmed that a neutral vessel cannot be destroyed but must be taken into a prize court for adjudication, but exceptions were

made for cases in which such conveyance of the prize to port would mean danger for the captor or for the military operations in which he was engaged. This declaration was never ratified. During the World War of 1914–18, the Germans were unable to take captured vessels into their own ports because of the British blockade, and therefore sank them. Further, the use of the submarine, which obviously could not take prizes into port or even save the lives of those on the vessel destroyed, extended the danger to neutral vessels. More than 800 neutral ships were sunk during the World War. In the European war which started in 1939, the greater use of the airplane made possible greater destruction of vessels—again with the impossibility of saving lives therein. Millions of tons of shipping, a large part of it neutral ships, were sunk without warning. Thus, because of new methods and machines of warfare, and because of the totalitarian character of modern war, the belligerent may be expected to destroy recklessly whatever neutral vessel comes within range of his suspicions or declared zones; it is inevitable that he should do so, and international law cannot prevent it unless neutral states combine to protect their rights by physical force, or unless the community of nations prevents war. In this interdependent world, shipping is as important a part of warmaking as are guns.

Neutral vessels in belligerent jurisdiction may be requisitioned for use by the belligerent, subject to adequate compensation. The uncertain term «angary» has been applied to this procedure. It is a sort of «eminent domain.» In modern war, the belligerents control the movements of neutral vessels to a very large degree without taking them over. Thus, the Allied Supreme War Council, during the World War, was able to tell neutral vessels when and where they should sail, what cargoes they could carry, and what could be unloaded at each port.

War and law are antithetical. As the range of modern war has increased, the protection which international law can give has diminished; this situation will continue until war is brought under control. Until that time, the neutral merchant vessel must face far greater risks than ever before in its search for profit during wartime. See also INTERNATIONAL LAW; INTERNATIONAL LAW, CHANGES IN; NEUTRALITY.

Bibliography.—Full references to literature and cases, as well as complete information to its date, may be found in the draft-treaty prepared by the Research in International Law, entitled *Rights and Duties of Neutral States in Naval and Aerial War,* published separately by the Carnegie Endowment for International Peace, and also as a supplement to *The American Journal of International Law,* Vol. 33, July 1939.

CLYDE EAGLETON,
Professor of International Law, New York University.

MERCIA, mĕr'shĭ-ą, England, the largest kingdom of the Saxon heptarchy, now comprised in the Midland counties on both sides of the Trent from the North Sea to Wales. Mercia was founded by Crida in 585. Like the other Anglo-Saxon kingdoms it had a stormy history, being almost continually at war with some of its neighbors. In 827 it was conquered by Egbert, who united the different kingdoms of England into one. As its frontiers extended to those of the other kingdoms, as well as to Wales, it derived its name from that circumstance (Anglo-Saxon *mearc,* march or boundary). See ENGLAND, *Geographical History.*

MERCIE, Antonin, ăñ-tō-năñ mĕr-sē-ā, French sculptor and painter: b. Toulouse, 30 Oct. 1845. He studied under Jouffroy and Falguière; won the first Prix de Rome in 1868; and in 1872 obtained a medal of the first class for his bronze statue of the young David, now in the Luxembourg. His masterpiece was 'Gloria victis' (1874), followed by a nude throned Juno (1877); a marble statue of 'Painting' (1890); 'William Tell,' now in Lausanne; monuments to Thiers, Meissonnier (in front of the Louvre), and Jules Ferry, and 'Napoleon' on the Vendôme Column. He painted a Venus, now in the Luxembourg. In 1891 he was elected an Academician. Died, 14 Oct. 1916.

MERCIER, Charles Alfred, American Creole author: b. McDonogh, near New Orleans, 3 June 1816; d. New Orleans, La., 12 May 1894. His father was a native of Louisiana and his mother, Eloise Le Duc, was a Canadian. At the age of fourteen he went to France and studied classical and modern literature at the College Louis-le-Grand. At first destined for the law he turned to literature; returned to Louisiana in 1838 and spent some time in Boston during which he perfected his knowledge of English. Returning to Paris, he published an Oriental story in verse, 'La Rose de Smyrne' in 1840; 'L'Ermite du Niagara,' a mystery play. In the next few years, Mercier traveled extensively on the continent and composed the drama 'Henoch Edesias,' which was lost during the revolution of 1848. After the revolution he studied medicine and returned to practise it in New Orleans, but soon returned to Paris. He disapproved of slavery but considered the Civil War as a triumph for Anglo-Saxon civilization and scored it in 'Du Pan-Latinisme ou la Necessite d'une Alliance entre La France et la Confederation du Sud.' After the close of the Civil War he returned to New Orleans and engaged in the practice of medicine. He continued his writing, however, and 'Le Fou de Palerme' appeared in 1873. In 1876 Mercier founded the Athenee louisianais, an organization having for its object the preservation of the French language in Louisiana. Thereafter much of his literary effort appeared in the *Comptes Rendus* of the Athenee. Of his later works, 'Emile des Ormiers,' the story of a Paris painter, and the drama 'Fortunia' have had the most enduring fame.

MERCIER, Desiré Joseph, Belgian cardinal, archbishop of Malines and primate of Belgium: b. 21 Nov. 1851 at Braine-l'Alleud; d. Brussels, 23 Jan. 1926. Educated at Louvain, Paris and Leipzig, he was ordained priest in 1874 and became professor of philosophy at the University of Louvain. Here he organized the Institut Supérieur de Philosophie, based on the teaching of Saint Thomas Aquinas and founded under the auspices of Pope Leo XIII. As a distinguished lecturer Professor Mercier —as he then was—earned a high reputation for literary and scientific abilities united with

zeal, leadership and exalted purpose. He wrote several volumes of note, e.g., *Les Origines de la Psychologie Contemporaine* (1897), *Métaphysique Générale* and *Critériologie,* which passed through numerous editions, as well as others of a less didactic character. He was also the founder of the *Revue Neo-Scholastique* when officiating as head of the school of neo-scholastic philosophy. On Feb. 8, 1906 it was announced that "Dr. Mercier, president of the Institute of Advanced Philosophy at Louvain," had been appointed archbishop of Malines. Though at first a general surprise, the appropriateness of selecting him to the episcopal bench soon became apparent. With energy and amiability he devoted himself to the administration of his diocese, and on April 15, 1907 was created and proclaimed cardinal and primate of Belgium. The German conquest of Belgium in the early stages of the European War brought him into world-wide prominence by the fearless and determined attitude he adopted toward the ravagers of his country. In the papal conclave of September 1914, after the death of Pope Pius X, a number of the assembled cardinals decided to give Mercier their vote in the election for a new pope as a demonstration of sympathy with Catholic Belgium. He was supported by the French and English cardinals, while the Germans and Austrians protested against what they called undue interference of politics in the highest spiritual functions of the church, and Cardinal Della Chiesa was ultimately elected. Cardinal Mercier arrived in London Sept. 12, 1914, and on the following day (Sunday), accompanied by the late duke of Norfolk, was received in audience by the king and queen. In the afternoon he witnessed a remarkable and enthusiastic demonstration in Westminster, organized by Irish members of Parliament and attended by many thousands of people. He returned to Belgium the same night and exerted himself during the long period of the German occupation to ameliorate the sufferings of his compatriots. He came into frequent collision with the German authorities, notably Baron Moritz Ferdinand von Bissing (q.v.). The cardinal's pastoral letters, collected and published by Burns and Oates (London 1918), form a series of earnest exhortations to the practice of Christian fortitude and hope amid the horrors and afflictions of war.

MERCIER, Honoré, Canadian lawyer, journalist and politician: b. Iberville, Quebec, Oct. 15, 1840; d. Montreal, Oct. 30, 1894. He was educated at Saint Mary's (Jesuit) College in Montreal and afterward studied law at Saint Hyacinthe, being admitted to the bar in 1865. During his legal studies (1862–1864) he was editor of the *Courier de Saint Hyacinthe,* the Conservative organ of the district; but as a journalist he was among those who opposed Canadian Confederation. This led him to abandon his editorship and to sever his connection with the Conservative Party. During the years immediately following the confederation of 1867 Mercier devoted himself to his profession, but in 1871 he reappeared in politics as the leader of the National Party (also called the Parti noir), whose leading aim was to curtail the power of the Dominion government in favor of provincial rights. On this platform he was elected to the federal Parliament for Rouville in 1872, but did not stand for re-election to the Parliament of 1873. After some four years devoted to the successful practice of law at Saint Hyacinthe, Mercier was elected (1879) to the legislative assembly of Quebec, being appointed solicitor general of the province in the ministry of M. Joly. On the defeat of the Joly administration in the same year, Mercier passed into the opposition, of which he presently became leader. In 1881 he left Saint Hyacinthe to practise law in Montreal. In 1885 the French Canadian population was thrown into a ferment by the trial and execution of Louis Riel, the leader of the North West Rebellion (q.v.). Mercier, heading the agitation thus occasioned, declared Riel to have been a "victim of the fanaticism of Sir John A. Macdonald." On the strength of the feeling thus aroused, the Conservative Party was defeated in the provincial elections of 1886 and Mercier found himself at the head of the administration. In this capacity he carried through the legislature the famous Jesuit Estates Act, a measure intended to compensate the Jesuits for the property confiscated by the crown at the time of the papal dissolution of the order. In spite of the agitation throughout Canada against the act the Mercier government was upheld in the election of 1890. In the same year grave charges of peculation were brought against the premier and his colleagues on the ground that a subsidy of $100,000, intended for the Baie des Chaleurs Railway, had been diverted to political uses. Investigation resulted in the dismissal of the ministry (Dec. 15, 1891), action which was ratified by the overwhelming defeat of the Mercier party in the election which ensued. The criminal charges brought against Mercier, as a result of this and a second official investigation, ended in a verdict of not guilty. Mercier remained a member of the assembly but with diminished influence and shattered health.

MERCUR, mėr'kėr, **James,** American soldier: b. Towanda, Pa., Nov. 25, 1842; d. West Point, N. Y., April 22, 1896. He was graduated from West Point in 1866 and commissioned in the engineering corps. He was engaged in surveys made under the government and in 1867–72 was assistant professor of natural and experimental philosophy at West Point, after which he was in command of an engineering corps and in 1876–1881 assisted in clearing the New York harbor of the obstructions at Hell Gate. He was professor of civil and military engineering at West Point from 1884 until his death. He published a revised edition of Mahan's *Permanent Fortification* (1887) and the original works, *Elements of the Art of War* (1888); and *Military Mines, Blasting and Demolitions* (1892).

MERCURIC CHLORIDE. See Corrosive Sublimate.

MERCURIC CYANIDE. See Hydrocyanic Acid.

MERCURY, mėr'kū-rĭ, the Roman god Mercurius who presided over commerce and gain. See also Hermes.

MERCURY, the nearest planet to the Sun, has been known from prehistoric times, though

most persons have never seen it. There is a tradition indeed that even Copernicus never did. This is due to the fact that, since its orbit is far inside that of the Earth, its angular distance from the Sun never exceeds 28°. This last occurs when the planet comes to aphelion at greatest elongation, when near perihelion it would be only 18°. Again, as Mercury is always near the ecliptic, it will best be seen when the latter is most nearly perpendicular to the horizon. This occurs for middle northern latitudes after sunset near the spring equinox and before sunrise near the fall equinox. Even then, by the time darkness has fallen, the planet is quite near the horizon or has set. So no one can ever observe Mercury under favorable night conditions, in fact the best observations are made in full daylight when the planet is higher in the sky. Being an inferior planet it has phases, being crescent when nearest us and quarter when near elongation.

The planet is yellowish in color and when brightest is about —1 magnitude. Older books make its brightness much less. Its apparent diameter can vary from 4."7 to 12."9. Its mean distance from the Sun is 36 million miles or 0.3871 astronomical units, and the eccentricity of its orbit is 0.206. This means that under extreme circumstances the planet may be as near as 48 million or as far as 138 million miles from us, at inferior and superior conjunction respectively. Its sidereal period is 88 and its synodic period 116 days. Its mean orbital velocity is 29 miles per second, and its orbit is inclined to the ecliptic 7°. Due to the orbit's great eccentricity the solar heat received at perihelion to that received at aphelion has the ratio 9:4. Its diameter is 3,100 miles which gives a volume of 0.06 that of the Earth. Its mass is very difficult to compute as the planet has no satellite. The best value is about 0.045 that of the Earth which then gives a density of 4 in terms of water. About the year 1800, observations by Schroeter a celebrated planetary observer, were supposed to indicate an axial rotation of nearly a day, but Schiaparelli, working in Italy in 1889, pretty clearly proved that the planet keeps the same face towards the Sun. Observations, even with the most powerful telescopes, are very difficult and markings on the planet very indistinct, but all recent evidence now tends to confirm Schiaparelli's conclusion. As with Venus observers are handicapped by the fact that when nearest us Mercury shows only a narrow crescent and in addition is angularly near the Sun. By the time half of its illuminated surface is turned towards us, it is already nearly an astronomical unit distant. Indeed Mercury is so near the Sun that body tides caused by the latter would slow up the axial rotation and eventually bring about the coincidence of its day and period. Nevertheless the orbit is so eccentric that there are enormous librations and due to them at most only 30 per cent of the surface is in perpetual night. Obviously an equal per cent has continuous sunshine while, for the rest, the Sun must rise a certain distance in the sky and then set in the same direction it rose once per revolution. The planet has no atmosphere detectable by either visual or spectroscopic observation. Nor, remembering its small mass, its nearness to the Sun, and the kinetic theory of gases could any atmosphere be expected. Its low albedo of 0.07 and the changing per cent of light with different phases indicate that the surface must be very rough, probably quite like the Moon, and for the same reasons. On the side in continual sunlight radiometric measurements give a temperature of 410°C. or enough to melt lead or tin. No measurable radiation could be detected from the dark side, which must be frightfully cold. Obviously life as we know it could not exist on Mercury: it is an even worse place than our Moon, due to more violent temperature changes. Otherwise they seem quite alike.

A planet's orbit is not a fixed thing but changes its shape and position slowly due to the mutual gravitational interactions of the other planets. The changes can, however, be calculated. Due to these the perihelion point of Mercury's orbit moves eastward nearly 10′ per century. But observations indicated an excess of about 40″ over theory. An explanation was sought in many ways. First a small planet was thought of whose orbit would be nearer the Sun. But such a planet cannot be found and now it is certain that it does not exist. Next the zodiacal light was used, which is caused by innumerable small particles in the plane of the ecliptic, and filling some of the space within our orbit. However, modern observations show that the mass necessary is out of all reason compared to what is found. Finally in 1915 the general theory of relativity by Albert Einstein predicted that Mercury's perihelion point would advance 43″ per century faster than the Newtonian theory demanded. As, within the probable errors, this is sensibly the value computed from observations, it is considered the first practical proof of Einstein's theory. Mercury is far the best object on which to make this test because of its high orbital velocity and, since the eccentricity of the orbit is great, it becomes relatively easy to determine the perihelion point with exactness. This cannot be done for Venus, since its orbit is so nearly a circle, and the other planets have too slow an orbital velocity.

At intervals the motion of Mercury causes it to pass directly across the face of the Sun. This phenomenon is called a transit. On such occasions observations with powerful telescopes should show traces of an atmosphere were any appreciable amount present, but the planet's outline is quite sharp. Transits also serve to give excellent positions of the planet. Beyond these uses they are merely interesting events. There are now about 13 per century. They take place in May or November. The next three will occur on Nov. 14, 1953, May 6, 1957 and Nov. 7, 1960.

CHARLES P. OLIVER.

MERCURY, or **MARKERY,** a perennial herb (*Chenopodium bonus-henricus*) of the natural order Chenopodiaceae. Like other members of its genus, it has mealy foliage and inconspicuous greenish flowers.

MERCURY, Medical Uses of. Mercury uncombined is used only for its bulk. As it is without medicinal effect, at one time as much as two pounds of uncombined mercury would be given for the purpose of mechanically dislodging some obstruction in the intestines. Triturated with some other substance it is valuable medicinally and produces specific mercurial effects, local and constitutional. Such compounds are "blue mass" (blue pill), mercury with chalk (gray powder), mercurial ointment and mercurial plaster. All mercurial compounds entering the circulation have a rather peculiar influence

over nutrition. This is especially true of salts of mercury, such as mercurous chloride or calomel, mercuric chloride or corrosive sublimate and mercurous iodide or the green iodide of mercury. In small doses, especially in syphilis, mercury has a definite toxic action on the spirochete which is the known parasite which causes syphilis. In large doses mercury acts as a corrosive poison and tends to inflame the mucous membrane of the mouth, stomach and intestines. Calomel and blue pill are largely used for their laxative effects. Mercury in the various forms of powder, ointment, lotion and plaster is used to remove body-vermin, relieve itching and as a remedy in certain skin affections. Mercuric chloride, known as corrosive sublimate, is a powerful antiseptic and is taken internally in very minute doses. See Toxicology.

MERCURY, or QUICKSILVER, a metallic element which has been known for many centuries and which is distinguished from the other metallic elements by the fact that it is liquid at ordinary temperatures. Mercury occurs native in the metallic form, but by far the larger part of it is obtained by distilling the native sulphide, cinnabar (Hgs), in a current of air which is regulated so as to burn the sulphur of the sulphide, while leaving the mercury in the metallic state. Cinnabar occurs abundantly at Idria, Austria, at Almaden, Spain, and at New Almaden, near San Francisco Bay, and it is from these sources that the mercury of commerce is chiefly obtained. It occurs as veins and disseminated deposits, the ores of which are believed to have been introduced by hot waters of magmatic (q.v.) origin. Spain is the largest producer and the chief output in the United States comes from California, though deposits are known in Texas and Oregon. Mercury freezes at 37.9° F. below zero and boils, at the ordinary atmospheric pressure (760 mm.), at 675° F. Its specific gravity at 32° F., when compared with water at 39° F., is 13.596. Its specific heat at ordinary temperatures is about 0.0331, and its average coefficient of expansion between 32° F. and 212° F. is 0.00010085 (Fahrenheit scale). The ratio of the specific heat of the vapor at constant pressure to its specific heat at constant volume has been found, experimentally, to be 1.666, which indicates that the molecules of the vapor are monatomic and that they behave, so far as their collisions among themselves are concerned, as though they were elastic spheres. (See Gases, Kinetic Theory of). Mercury may be freed from dust and dirt by filtering it through leather. To remove tin, lead and other dissolved metals, the mercury may be left for some weeks in contact with concentrated sulphuric acid and subsequently digested with dilute nitric acid; or it may be several times distilled. Various other modes of purification are also known.

The metal is chiefly used, in the arts, for the extraction of gold from crushed ore or fine gravel, the ore being washed by a gentle stream of water over a copper plate which is amalgamated with mercury. The gold particles, being heavy, sink through the water so as to come into contact with the copper plate, where they are held by the mercury in the form of a gold amalgam. (See Gold and Amalgam). In physics, mercury is also greatly used for filling thermometers and barometers, and for many other purposes. It is likewise used in medicine, both in the metallic form and in its compounds with other elements. Metallic mercury, when rubbed up in a mortar with confection of roses until its globules are so fine as to be indistinguishable to the eye, is known as "blue mass" and is administered in the form of pills, as a cholagogue.

Mercury has the chemical symbol Hg (from "hydrargyrum," its Latin name), and an atomic weight of 200.3 if O = 16, or 198.8 if H = 1. It forms two oxides, each of which give rise to a series of stable salts. The metal does not oxidize upon exposure to air at ordinary temperatures, but when heated nearly to its boiling point in air or in oxygen it slowly oxidizes, with the formation of mercury monoxide (or mercuric oxide), HgO. When prepared in this manner the monoxide is crystalline and red, and for this reason it is familiarly known as the "red oxide." The same substance may be prepared in an allotropic form by precipitating a solution of mercuric nitrate by the addition of caustic potash, the monoxide then coming down as an amorphous yellow powder. The red oxide turns black when strongly heated, but recovers its color upon cooling. When heated to redness the monoxide decomposes into metallic mercury and free oxygen. It can, therefore, be used as a source of oxygen; and it was in fact by heating this substance that oxygen was first discovered by Priestley. By acting upon the red oxide or upon metallic mercury by excess of nitric acid, mercuric nitrate, $Hg(NO_3)_2$, is formed; while if nitric acid is allowed to act upon excess of mercury, mercurous nitrate, $HgNO_3$, is obtained. The corresponding sulphates of the metal are obtained by acting upon metallic mercury with sulphuric acid, mercuric sulphate ($HgSO_4$) or mercurous sulphate (Hg_2SO_4) being obtained, according to the conditions of the experiment. Mercuric sulphide, HgS, which occurs native as the mineral cinnabar, and which is also known as vermilion, is bright red in color and may be prepared artificially by heating mercury with sulphur, or by passing sulphuretted hydrogen gas through a solution of mercuric salt. When obtained in the latter way it comes down as a black amorphous powder, which may be brought into the normal red crystalline form by sublimation. Mercury forms two chlorides which are extensively used, especially in medicine. Mercuric chloride (also known as "bichloride of mercury" or "corrosive sublimate"), $HgCl_2$, is prepared by heating a mixture of equal parts of mercuric sulphate, $HgSO_4$, and common salt, NaCl; the reaction being $HgSO_4 + 2NaCl = HgCl_2 + Na_2SO_4$. The bichloride is fairly soluble in water and dissolves readily in a solution of sal ammoniac. It is also quite soluble in alcohol. It crystallizes in the trimetric system, melts at 509° F. and boils at 563° F. It is intensely poisonous and is one of the most powerful germicides known. It is used in surgery and medicine as an antiseptic and disinfectant, and is occasionally administered internally in very small doses. Mercurous chloride, HgCl (more familiarly known as "calomel," or as the "mild chloride"), is a white powder, insoluble in water and is greatly used in medicine, both as a cholagogue and otherwise. It may be prepared in various ways, but the usual method is

by heating four parts of corrosive sublimate with three parts of metallic mercury; the mercury combining with half of the chlorine of the corrosive sublimate, as indicated by the equation $HgCl_2 + Hg = 2HgCl$. The calomel sublimes and must then be ground to a fine powder and thoroughly washed, in order to remove any free soluble corrosive sublimate that may not have been decomposed. The so-called "white precipitate," which is obtained when ammonia is added to a solution of corrosive sublimate, has the composition NH_2HgCl. Mercurous oxide, or "black oxide of mercury," Hg_2O, may be obtained as a black powder by digesting calomel with excess of caustic potash. It decomposes into the red oxide and metallic mercury upon exposure to light, or upon being heated to the boiling point of water. Many other compounds of mercury are known. See STRATEGIC AND CRITICAL MINERAL SUPPLIES.

MERCURY VAPOR LAMP. See VAPOR LAMPS.

MERCY, Fathers of, Roman Catholic religious congregation founded on the restoration of Louis XVIII, 1814, and approved of by the Pope (1834) under the title 'Society of the Priests of Mercy.' The object of the society is the conversion of sinners by mission preaching and the practice of the corporal works of mercy. In 1839 the order founded houses in New York and Saint Augustine, Fla., and the fathers have churches for the French population in Brooklyn and Manhattan. The mother house was originally at Paris, but was removed to Rome in 1903 as a result of the Association Law. Consult Delaporte, 'Vie de Jean-Baptiste Rauzan' (1857).

MERCY, Sisters of, a name given to members of several religious communities founded for the purpose of nursing the sick at their own homes, visiting prisoners, attending lying-in-hospitals, superintending the education of females and the performance of similar works of charity and mercy. Communities of Sisters of Mercy are now widely distributed over Europe and America. There are also religious orders under the same name connected with the Anglican Church. The term is applied more specifically to the Order of Our Lady of Mercy, a Roman Catholic order founded for the objects above enumerated in Dublin 1827. The first house in America was established in Pittsburgh, Pa., 1843, and from it have sprung 65 convents. Consult 'Leaves from the Annals of the Sisters of Mercy' (1881). See MCAULEY, CATHERINE.

MERCY-SEAT (Heb. *Kappo'reth,* covering or lid, that is, of the sacred ark in the ancient Jewish tabernacle), an unfortunate and inappropriate term as applied to the cover of the chest or ark containing the two tables of the law and overspread by the wings of the Cherubim. Between these wings appeared the Shekinah or fiery symbol of the divine presence hovering over the mercy-seat, which consisted most probably of a sheet of the finest gold (Ex. xxv, 17, etc.; xxx, 6; xxxi, 7, etc.). The New Testament writers seem to hold that the term contains by implication the idea of the propitiation (q.v.) (Heb. ix, 5; Rom. iii, 24). The high priest sprinkled on it the blood of the yearly atonement, and some writers think that the term covering as applied to it refers more to the covering of or atonement for sins than to its use in covering the treasures of the ark. In any case the idea of a seat, as if the expression in Psalms xcix, 1, "he sitteth between the cherubims" referred to the earthly tabernacle, is inappropriate. Consult Pratenias, 'De Judæa Arca' (1727); Werner, 'De Propitiatoria' (1695). See SHEKINAH.

MEREDITH, George, English poet and novelist: b. Hampshire, 12 Feb. 1828; d. London, 18 May 1909. Details of Meredith's life are meagre; little is known of his parentage or of his education except that he was sent to school in Germany and later studied law, which he gave up for literature. For a time he was a pupil of T. L. Peacock (q.v.), whose daughter became his first wife. His residence was for some years at Box Hill in Surrey.

His first work in literature was a volume of poems published in 1851. This was followed, in 1856, by 'The Shaving of Shagpat,' a brilliant, fantastic Oriental tale in which some interpreters have professed to see a political satire. In 'The Ordeal of Richard Feverel' (1859), however, he began the course of studies in human temperament which have made his name famous. The novel, unquestionably one of the most powerful in the language, deals with the ordeal of adjustment to the world of a high-spirited youth; it is the conflict between temperament and desire, represented in the hero, and a variety of conventions, most rigidly typified in the "system" of his father, Sir Austin Feverel. The effect of the book is chiefly tragic. 'Evan Harrington' (1861), the next novel, is wholly comic in idea; the characters are embodiments of various "humors," most strikingly represented in the intriguing Countess; the plot, as in all of Meredith's novels, is quite secondary in interest and springs from the characters. 'Modern Love,' a sequence of brilliantly phrased, intricate, 16-lined sonnets, was published in 1861. 'Emilia in England,' now called 'Sandra Belloni,' appeared in 1864, and its sequel 'Vittoria' three years later. The story is that of a young Italian girl of unaffected manners and character and her life among people of very diverse temperaments and social ideas; the theme of the novel may be regarded as the conflict, among very real people, of the genuine with the sentimental character. Between the two novels appeared, in 1865, 'Rhoda Fleming,' perhaps the simplest of all Meredith's novels in style and a powerful study in character. It deals, on the whole, with a conventionally more humble order of society than is usually found in Meredith's novels, and is rather more direct, but few things in fiction are more impressive than the almost instinctive steadfastness of the heroine or more gloomy than the spiritual confusion that she tries to set in order. In 'The Adventures of Harry Richmond' the note is again chiefly comic. Much of Meredith's best work lies in the freshness of the varied scenes of this book, and in the hero's father is perhaps as typical a character of the novelist as can be found, a man whose adventurous fancy and devotion to his son "informs" numberless odd and extravagant acts. Another excellent study of a different sort is 'Beauchamp's Career' (1876). It is the analytical, yet lively, story of a young man whose earnestness of character and whose activity caused him, from a conventional point of

view, to fail in life. Like other of Meredith's novels it is a great contribution to our understanding of the varieties of human temperament and to our sympathy with them.

In 'Beauchamp's Career' perhaps more than in any of his preceding novels Meredith directly explained his aim in drawing character; it was to present a type of motive and to show how it dominates and gives unity to a series of acts. The motive which causes action is, so to speak, temperamental rather than deliberate; in typical examples like the Countess in 'Evan Harrington,' or Beauchamp, for instance, Meredith is interested in the expression of temperament rather than a story. The Countess, on the face of the matter, wished for the social advancement of her family; what she really wanted was scheming for the sake of scheming and her social ambitions were but the medium of expression. This manner of approaching character, indeed, dominated all the character drawing in Meredith's novels, but it was not expressed as a deliberate theory until the publication, in 1877, of 'On the Idea of Comedy and the Uses of the Comic Spirit.' The essence of this essay is that comedy is one of the most wholesome and effectual ways of probing and purifying the ills of the world, that good comedy, as in the plays of Molière, really enables the reader to recognize what is genuine and discard what is sentimental; unfortunately, instead of good comedy we often are treated, in most literature, to painful moralizings. Meredith's fullest and finest expression of this idea is in his 'The Egoist' (1879), unquestionably his masterpiece and one of the chief glories of English fiction. Egoism, that love of self which prevents men from seeing things in their true relations, is one of the fundamental failings of mankind and Meredith has drawn it, in the inimitable Sir Willoughby Patterne, as a figure of colossal proportions. The novelist's skill and dispassionateness as an artist was never better shown than in the fact that he refuses to give conventional rewards and punishments; for the hero's unfailing egoism permits him in the end to turn to the flattering of his vanity what would ordinarily be regarded as humiliation.

Pursuing his end, an analysis and a synthesis of the springs which govern action, Meredith in his next novel, 'The Tragic Comedians' (1880) took a story from contemporary European court life and explained it as a piece of dramatic psychology. The comparative shortness of the novel makes it a good study of the author's method. This novel, too, indicated a tendency on his part to depict the motives and the psychology of people actually in existence rather than, as in 'The Egoist' and its predecessors, to draw the embodiment of a type of "humor." This tendency was certainly evident in his next novel, 'Diana of the Crossways' (1885), his greatest popular success, and is shown in the fact that certain of the incidents and characters excited curiosity as, to their originals. It is manifest also in his last three books, 'One of Our Conquerors' (1890), 'Lord Ormont and His Aminta' (1894) and 'The Amazing Marriage' (1895), which are perhaps less broadly representative and more particular than his earlier novels. Meredith's writings also include four short stories, 'The Tale of Chloe,' 'The House on the Beach,' 'Farina' and 'The Case of General Ople and Lady Camper.'

Meredith, who was one of the last great novelists to hold over, as it were, from the age of Victorian literature, belongs to the so-called psychological school, of which the great popular representative is George Eliot, with whom he is practically contemporary. He differs from her in several important respects: The comedy of character (as the term is understood with Cervantes and Molière) as well as the tragic side of life, is reflected in his pages. His attitude is detached and impersonal and he never allows his sympathies to intrude upon his study of the type he is treating, a characteristic which accounts for the criticism sometimes made that he lacks temperament and which is doubtless one of the reasons for his comparative unpopularity. He is more interested in his characters as types of temperament than as individuals, and in this field he has perhaps represented the greatest range and variety of human motive that is to be found in English fiction. Taking strata of society, on the whole, conventionally above those treated by George Eliot, he has made them representative of a great variety of "comic" motives. As a moralist, his attack has been upon those types which are broadly termed sentimental, and in this respect his pictures of such men as Wilfred Pole and Willoughby Patterne are inimitable. The person that he most approves is the simple, considerate, intelligent being, well represented in such minor heroes as Merthyr Powys, Vernon Whitford, Dartrey Fennellan and Tom Redworth, and pictured to the height of brilliancy in his real heroines. In no other novelist, in no English writer except Shakespeare, can be found so splendid a galaxy of women: Rose Jocelyn, Janet Ilchester, Renée, Cecilia Hilkett, Jenny Denham, Clara Middleton, Emilia, Carinthia Jane and many others, as well as such older ladies as Lady Jocelyn and Lady Charlotte Eglett, are the best tribute to womankind that English literature possesses, and the creation of them is an achievement of the very first rank. His style is frequently criticized as involved and epigrammatic, but no novel contains passages of greater poetical charm. See DIANA OF THE CROSSWAYS; EGOIST, THE; ORDEAL OF RICHARD FEVEREL, THE.

Bibliography.—The best complete American edition of the poems and novels is by Messrs. Scribner, in 16 volumes. Commentary is scattering and appears chiefly in the form of contemporary reviews. Consult Brownell, 'Victorian Prose Masters' (1901); Lynch, Hannah, 'George Meredith' (1891); and, for a varied symposium, LeGallienne, 'George Meredith, Some Characteristics; with a Bibliography by John Lane'; and for his place in the history of the novel, Cross, 'The Development of the English Novel' (1899). Consult also Ellis, S. M., 'George Meredith: His Life and Friends' (London 1919).

W. T. BREWSTER,
Professor of English, Columbia University.

MEREDITH, Louisa Anne Twamly, Australian author and artist: b. Birmingham, England, 20 July 1812; d. Hobart Town, Tasmania, 21 Oct. 1895. She had already published a volume of verse (1835); and 'The Romance of Nature,' illustrated by herself (1836), before

she married her cousin Charles Meredith (1839) and removed to Australia, whence they went to Tasmania five years later. She continued her literary activity till the end of her long life and for many years before her death had been the most prominent Tasmanian author. Among her books, many illustrated by herself, are 'My Home in Tasmania' (1852); 'Over the Straits' (1860); 'Tasmania: Friends and Foes, Feathered and Furred' (1880). Her prose works were popular in Australia and had also a circulation in England and this country; and her verse, of which she published several collections, was at once pleasing and unpretentious.

MEREDITH, Owen, the pseudonym of Bulwer-Lytton. See LYTTON, EDWARD ROBERT BULWER.

MEREDITH, Samuel, American patriot and first Treasurer of the United States: b. Philadelphia, Pa., 1740; d. 10 March 1817. His father was a Welshman and a friend of George Washington. Meredith became a member of the Pennsylvania colonial legislature, and when the American Revolution broke out he entered the Colonial army as major, took part in several battles and was made brigadier-general for gallant services. He gave £10,000 in silver for carrying on the war, and was exiled from Philadelphia when the British occupied it. Meredith served in Congress in 1787–88 and in 1789 became the first Treasurer of the United States, advancing to the government, on taking the office, $20,000 and later $120,000, for which he was never reimbursed. He remained in the office of Treasurer until 1801.

MEREDITH, SIR William Ralph, Canadian jurist: b. Westminster, Ontario, 31 March 1840; d. 22 Aug. 1923. He was educated in the University of Toronto and was admitted to the bar in 1861, beginning practice in London, Ontario. He became queen's counsel in 1876 and in 1881 removed to Toronto. In 1872 he entered the provincial legislature of Ontario as member for London and for 16 years he was leader of the Conservative opposition during the long reign of Mowat as Premier. In that position he showed a disposition to subordinate provincial rights to those of the Dominion; and he was an advocate of manhood suffrage, secret ballot, the enlargement of powers to municipalities and workmen's compensation. In 1894 he was appointed chief justice of the Court of Common Pleas and in 1912 chief justice of Ontario. In 1896 he was appointed a commissioner for the revision of the provincial statutes, and in 1905 he was one of the commission that investigated the affairs of Toronto. He was knighted in 1896, and became chancellor of the University of Toronto in 1900.

MEREZHKOVSKI, Dmitri Sergeyevich, Russian critic and novelist: b. Saint Petersburg, 1865. He was educated in his native city and published his first volume of verse at the age of 23. In 1893 he published an essay on the decadence of Russian literature which attracted general attention. In 1901–02 appeared his 'Critical Studies of Tolstoy and Dostoyevsky as Men and as Artists' and 'The Religion of Tolstoy and Dostoyevsky,' which proved him a critic of high order. Next there appeared his trilogy of historical novels dealing with the perennial conflict between Christianity and paganism. Collectively known as 'Christ and Antichrist,' this work has appeared in most modern languages. It includes 'Smert Bogov' (Eng. trans., 'The Death of the Gods,' London 1901), in which the chief character is Julian the Apostate; 'Voskresenie Bogi' (Eng. trans., 'The Forerunner,' ib. 1902) with Leonardo da Vinci as chief character; and 'Antikhrist: Pëtr i Aleksyey' (Eng. trans., 'Peter and Alexis,' London 1905). He also wrote the dramas 'Paul I' (1908) and 'Alexander I' (2 vols., 1913). Consult collected edition of his works (15 vols., Saint Petersburg 1911–12) and Phelps, W. L., 'Contemporary Russian Novelists' (Boston 1913).

MERGANSER, or **FISH-DUCK,** a duck of the genus *Mergus,* distinguished by the slender cylindrical bill, the upper mandible terminating in a strong hooked "nail," and the margins presenting the appearance of rows of tooth-like processes. The most widely distributed is the red-breasted (*Mergus serrator*), known as sheldrake in America where it is less numerous than in the Old World. The goosander (*M. merganser*) and the nun or smew (*M. albellus*) are familiar European and Asiatic species, while the hooded merganser (*Lophodytes cucullatus*) or sawbill is familiar in North America. The mergansers feed chiefly upon fishes and swim and dive after their prey with great ease and dexterity. They are essentially northern in their distribution, breed in the far north and migrate southward on the approach of the colder season. The nest is built of grass and roots and is lined with down. It is usually placed in a hollow of the bank near water, but some species prefer the greater security of a hollow tree. The flesh is coarse and rank. Eight or 10 species are known in various parts of the world. The female alone incubates, but the male watches near the nest. From 8 to 14 eggs are laid and the young enter the water as soon as they are hatched.

MERGENTHALER, mĕr'gan-tä-lèr, **Ottmar,** American inventor: b. Württemberg, Germany, 10 May 1854; d. Baltimore, 28 Oct. 1899. He was a watchmaker by trade; came to the United States at 18, entered the employ of the United States government at Washington, where he kept clocks and electrical bells throughout government buildings in order; improved apparatus used in the signal service, and in 1876 removed to Baltimore, where he devoted himself to perfecting a type-setting machine. On this he spent several years, his scheme going through four stages, the last of which was the linotype (q.v.). When he had patented this machine he had much difficulty in introducing it. It was perfected by the addition of the Rogers spacer and numerous minor inventions by Philip T. Dodge and others, brought its inventor large profits and is now in very common use in large printing establishments. Mergenthaler also invented a machine for making fruit gift-baskets of veneered wood.

MERGER, *in law,* the sinking or obliteration in conveyancing of lesser estates or property into greater ones, or the consolidation of two or more estates; a term used in financial or business circles, meaning the consolidation or combination of a particular class of manufactories, railroads or other business interests;

generally in the nature of a trust. Late in the 19th century it became common in the United States for a group of corporations, which it was desired to bring together for monopolizing an industry, to merge by forming a holding company, which took over the majority stock of each subsidiary company in the merger and gave in exchange the stock of the holding company. To test the validity of such mergers a suit was brought against the Northern Securities Company, and after exhaustive arguments and much delay the United States Supreme Court declared that the procedure was "in restraint of trade." Since then corporation mergers have ceased. The principle still holds good, however, in both civil and criminal law, that the lesser may merge into the greater. In contracts the acceptance of a high grade of security is held to extinguish the lower grade. When a bond is given for the performance of a contract the obligation to fulfill the contract is merged in the bond as the higher obligation. See also TRUSTS.

MERGUI ARCHIPELAGO, mûr-gwē′, a chain of about 800 islands in the Andaman Sea, off the coast of Tenasserim in Burma, forming a part of the Lower Burma district of Mergui which has an area of 10,906 square miles. The islands are generally covered with jungle growth, and present many picturesque features, rising at some points to the height of 3,000 feet. The largest island is Tavoy, and others are King, Elphinstone, Ross, and St. Matthew islands. There is some mining of tin and tungsten on these islands and there are rubber plantations on several of the larger ones.

The chief town is Mergui, situated on a small island off the coast of Burma, with a population (1931) of 20,405. The locality is one of the dampest on the globe, the rainfall exceeding 100 inches annually. The inhabitants, mainly Selungs, give little attention to agriculture, obtaining a sustenance mainly by fishing, pearl gathering, and selling edible birds' nests. They are peaceful and industrious, but few in number. Pop. of Mergui District (1941) 180,827.

MERIDA, mā′rē-thä, **Carlos,** Mexican painter: b. Guatemala, Dec. 2, 1893. He studied in Paris (1910–1914) under Kees van Dongen and Anglada Camarasa, and returned to Guatemala where he began to explore the folklore themes of Central America. In 1919 he went to Mexico and held his first exhibition and in 1920 he joined a group of revolutionary Mexican painters under the leadership of David A. Siqueiros. With them he painted frescos in several government buildings, including in 1923 the children's library in the Ministry of Education Building, Mexico City.

A second trip to Paris (1927–1929) turned his interest to surrealism, and on his return to Mexico City, as professor of painting at the Escuela Centrale de Artes Plásticas, he propagated this form of art. He has exhibited in the United States and in Mexico and has written and illustrated *Tres motivos, huecograbado* (copperplate engravings, 1936); *Modern Mexican Artists* (1937); *Ten Interpretive Guides on Mexican Frescos* (1937); *Dances of Mexico* (10 color lithographs, 1938); *Carnival in Mexico* (1939); and *Mexican Costumes* (1941).

Mérida's painting has always been highly personal, emphasizing the abstract and symbolic aspect of the art. Out of his study of the Indian customs, dances, and art, he has evolved an expression that is truly poetic. Although he works in a variety of media, some of his finest painting has been done in watercolor. His handling of this medium is one of the most original and sensitive of the present century.

MERIDA, city, Mexico, capital of the State of Yucatán. It is situated on part of the great, low plain which comprises most of the state and is surrounded by henequen (sisal hemp) plantations. The climate is tropical. Numerous metal windmills in and around the city provide water from wells. The city was founded in 1542 by Francisco de Montejo the younger on the site of a Maya city called T'ho, and the early buildings were largely built of the stones from Maya temples and other native structures. The city has a strong Spanish tradition which is reflected in its architecture. The population, however, is largely Maya. The Montejo house, which dates from 1549, is located on the main plaza, as is the cathedral (1561–1598).

Mérida is the center of the Yucatán henequen industry, manufacturing rope, cordage, and coarse fabrics for sacking, and dyeing and weaving finer fabrics for small bags and hats. Cotton and leather goods are also made and there are numerous bottling works and breweries.

Some 75 miles to the east are the extensive and magnificent ruins of Chichén Itzá (q.v.), the sacred city of the Maya civilization during the New Empire. This place was settled by the Itzá people during the 6th century A.D. and reached its highest point 500 to 700 years later, to be completely abandoned about 1450. Even more elaborate in its architecture, although smaller in extent, is the Maya city of Uxmal (q.v.) whose ruins are about 55 miles south of Mérida. This was founded by the Xiu toward the end of the 10th century and abandoned about the same time as Chichén Itzá.

For many centuries Mérida was the most isolated of the larger Mexican cities since its only connection with the rest of the republic was by sea through Progreso, Yucatán's chief port, 23 miles distant by rail and highway to the north. With the coming of air transportation, this isolation was somewhat alleviated, for the Pan American Airways established a large airfield just outside the city. However, there was no land connection, except for the road and narrow gauge railroad which went only as far south as Campeche, until this latter railroad was linked with the rest of the republic in 1950. Other principal buildings in Mérida are those of the University of Yucatán and the Archaeological Museum. Pop. (1940) 96,852.

MERIDA, commune, Spain (Roman name AUGUSTA EMERITA), in the province of Badajoz, situated on the Guadiana River, 33 miles east-northeast of Badajoz. It is unique in Spain, and is in some points a rival of Rome itself because of the number and magnitude of its remains of Roman antiquity, built when it was the capital of the province of Lusitania. The Guadiana is here crossed by a Roman bridge of 64 arches (originally 81, but 17 were destroyed in 1812), with a length of 2,575 feet and a breadth of 26 feet. There is another Roman bridge over the Albarregas nearby, 450 feet long, 25 feet wide, and still quite perfect, in spite of the traffic of 18 cen-

turies. Among the other noteworthy monuments of antiquity are an old Roman castle, later a Moorish alcazar, constructed out of a temple dedicated to Diana, several aqueducts, a triumphal arch built by Trajan, a colonnaded theater, an ancient amphitheater, and a circus.

Mérida was founded in 23 B.C. by Augustus, and flourished in great splendor under Roman and Moor until 1228, when it was taken from the Moors by Alfonso IX, after which it began to decline. The city fell to the insurgents in the early stages of the Spanish Civil War (1936–1939). Pop. (1940) 22,440.

MERIDA, town, Venezuela, capital of the State of Mérida, 5,384 feet above sea level, 30 miles south of Lake Maracaibo, at the foot of the Sierra Nevada de Mérida, which tower to a height of 15,000 feet. It was founded in 1558 by Juan Rodriguez Saurez, and is situated on the Venezuela-Colombia transandean highway. It was almost totally destroyed by an earthquake in 1812 and again seriously damaged in 1894.

It is the seat of a bishop, contains a fine cathedral, and is the site of Los Andes University, one of the two national universities of Venezuela, and a Jesuit college. It has a hospital and several high schools. Its manufactures are woolen and cotton goods, tobacco products, cordage, furniture, and vegetable oils. Pop. (1950) 24,994.

MERIDEN, mĕr'ĭ-d'n, city, Connecticut, in New Haven County, at an altitude of 190 feet, 17 miles northeast of New Haven, served by the New York, New Haven and Hartford Railroad, modern highways, and a municipal airport. It is the industrial center of a truck farming area, has brass and iron foundries, and manufactures plated and sterling silverware, ball bearings, lighting fixtures, plastics, carburetors, oil filters, household appliances, telephones and signals, hardware, and airplane accessories.

The silver industry, for which the city is noted, developed from its pewter button and tin shops of the late 18th century. The manufacture of Brittania ware was begun in 1808, and in 1852 numerous small plants combined to form the Meriden Brittania Company. In 1857 this company bought the Rogers plant in Hartford where, in 1847, the Rogers brothers had discovered a successful method of plating other metals with silver by electrolysis. They came to Meriden to manage the local company, and in 1898 it combined with several others to form the International Silver Company. A tuberculosis sanatorium and a state reform school for boys are located here.

Settled in 1661 and named for the English home of an early landed proprietor, it was incorporated as a town in 1806, as a city in 1867, and consolidated in 1922. It has a mayor and council, and a municipally owned water supply system. Pop. (1950) 44,088.

MERIDIAN, mĕ-rĭd'ĭ-ăn, city, Mississippi, seat of Lauderdale County, at an altitude of 341 feet, 96 miles east of Jackson, and served by the Southern (Alabama Great Southern; New Orleans and Northeastern), the Gulf, Mobile and Ohio, and the Illinois Central railroads, and an airport with scheduled service. The region about the city comprises areas of forests and of fertile farmlands which produce cotton, corn, sweet potatoes, strawberries, peaches, melons, and pecans. In the city there are extensive railroad shops, stockyards, lumber mills, cotton gins, cottonseed oil and grit mills, and brick, creosoting and cement plants. The Meridian factories produce hosiery, textiles, mattresses, and shirts. In connection with the lumber industry, wallboard is manufactured. The town has a public library and in the school system separate provision is made for white and Negro students. The city is the seat of the East Mississippi Insane Hospital.

Interesting points are the arboretum in Highland Park, the grave of a gypsy queen in Rose Hill Cemetery, and the Scottish Rite Cathedral. The state fair and dairy show is held at Meridian in the fall, and in April, Confederate Memorial Day is publicly observed. There is a federal agricultural experiment station nearby. Meridian has commission form of government, and a city-owned water supply system.

Settled in 1831, it was strongly developed by the advent of the railroad in 1854, becoming a supply depot and troop center during the Civil War. Gen. William T. Sherman entered Meridian on Feb. 16, 1864, with 20,000 troops, after marching virtually unopposed from Vicksburg. Here his troops burned the arsenal, extensive storehouses, and cantonments, while over 10,000 men were employed in a systematic destruction of the railroads to and from the city. Over 125 miles of rail were torn up and 61 bridges and trestles were burned, rendering Meridian useless as a railroad center for the rest of the war. Thereafter, the transporting of supplies eastward from Mississippi was seriously interrupted for a long time and was greatly impeded up to the close of the war. After the Civil War, Meridian was quickly rebuilt, again becoming a rail center, and in the early part of the 20th century, new industries began to be attracted there. Pop. (1950) 41,893.

MERIDIAN, one of the imaginary north and south lines on the surface of the earth that may be conceived of as passing through both poles and serving to indicate the longitude of places, and with a parallel of latitude mark their exact position. If one conceive the earth sliced into on one of these lines, the resulting surface is the plane of the meridian. There are also corresponding lines called astronomical or celestial meridians, which are imaginary circles of the celestial sphere passing through the poles of the heavens and the zenith of any place on the earth's surface. These correspond exactly to the geographical meridians, that is, the celestial is exactly above the geographical meridian of any place. Every place on the globe has its meridian, and when the sun arrives at this line it is noon or midday, whence the name (Latin, *meridianus—medius,* middle, and *dies,* day). (See LONGITUDE.)

The inconvenience arising from having a fixed meridian in different countries is sufficiently obvious, and geographers, navigators and astronomers have all found it frequently a source of confusion. After years of fruitless discussion the question of a reference or first meridian for the world came before an international conference held at Washington, in 1884. There, although the representatives of France and Brazil dissented, it was agreed to recommend the meridian of Greenwich both as the astronomical and as the geographical reference meridian of the world, longitude to be reckoned east and west from this

up to 180°. At the same time it was advised that the astronomical day should begin at midnight, mean Greenwich time, the hours for astronomical purposes being reckoned as before from 0 to 24. This arrangement began on Jan. 1, 1885. The change of time has had some importance for astronomers, but ordinary civil time is still computed much as before. The zone system of reckoning standard time has been adopted throughout the world. In the United States, since 1883, there have been four zones: the Eastern, taking time from the meridian of 75° W. (5 hours slow on Greenwich time); the Central, with standard meridian 90° W. (6 hours slow); the Mountain, 105° W. (7 hours slow); and the Pacific, 120° W. (8 hours slow). The magnetic meridian at any place on the earth's surface is the horizontal line along which a freely suspended compass needle points when influenced only by the earth's magnetism.

MERIMEE, mā-rē-mā', **Prosper,** French man of letters: b. Paris, Sept. 28, 1803; d. Cannes, Sept. 23, 1870. After attending the Collège Henri IV, Mérimée studied law, but never practiced, preferring to enter the civil service. Following the revolution of July 1830 he was made secretary to the ministers of commerce and marine, and in 1831 he was appointed inspector of ancient monuments. In 1844 he was elected a member of the French Academy, and in 1853 he became a senator of France; in 1860 he was made commander of the Legion of Honor. He began his literary career under the pseudonym "Joseph Lestrange" with two clever mystifications, *Le Théâtre de Clara Gazul* (1825), and *La Guzla* (1827), which he published as translations respectively of the plays of a Spanish actress and of Illyrian folk songs. These he followed with a historical novel, *Chronique du Règne de Charles IX* (1829). He also published several important works connected with his duties as inspector of ancient monuments, and he was the author of *Colomba* (1840), a very popular novel of the Corsican vendetta; *Carmen* (1847), a romance upon which the famous opera *Carmen* by Georges Bizet is founded; *Lettres à Une Inconnue* (1873), his most famous work, which throws an interesting light upon his enigmatical character; *Lettres à Une Autre Inconnue* (1875); *Lettres à Panizzi* (1881); and *Une Correspondance Inédite* (1896). The four works last named are Mérimée's most characteristic writings, revealing him as a loyal, devoted friend. They differ widely from his other works which, though often brilliant, are hard and unsympathetic; while these are tender and romantic.

A man of a melancholy, skeptical, and sensitive temper, and endowed with a powerful intellect, he was one of the greatest masters of imaginative prose in France in the 19th century. See also Carmen; Colomba.

MERINO, a woolen or worsted fabric, introduced about 1826, and so named because made from the wool of merino sheep. The word is originally the title of an inspector of sheep pastures in Spain, and became attached to the short-wool Spanish sheep. The breed did not originate here, however, being imported from Africa by the Moors and bred by the Spanish. The wool was so highly regarded that merino sheep have been exported for breeding all over the world, but especially to Australia. See also Wool.

MERIONETHSHIRE, měr-ĭ-ŏn'ĕth-shĭr, county, Wales, bounded on the north by Caernarvon and Denbigh, on the east by Denbigh and Montgomery, on the southeast by Montgomery, on the south by the estuary of the Dyfi (Dovey), and on the west by Cardigan Bay. The area is 660 square miles. The surface is rugged and hilly; the highest peak is Cader Idris (2,927 feet). Rivers include the Dyfi, Dee, and Mawddach. Bala Lake, in the eastern part of the county, is the source of the Dee; it is the largest natural lake in Wales. Limestone and slate are quarried, and there are deposits of manganese ore. There is much pasture land, and the small, hardy Welsh ponies are raised. Dolgelly is the county town; it has replaced Harlech, the ancient capital of Gwynedd (now included in Caernarvonshire, Denbighshire, and Merionethshire), and a center of resistance to the English. Pop. (1951) 41,456.

MERIT, Order of, is a British order designed as a special distinction for eminent men and women without conferring a knighthood upon them. It was created by King Edward VII on June 26, 1902, and is awarded by the sovereign without ministerial advice. Alone among royal honors, the O.M. confers no precedence and no stated position at court functions; and no sum of money, no perquisite, accompanies it. The initials O.M., when written, are placed before any others except those denoting membership in the four great orders of chivalry; and the red and blue enamel cross of the order is not returned at the holder's death. Membership is limited in number to 24 living persons, with the addition of foreign honorary members. The Order of Merit is highly prized in Britain, and it is the only honor which, so far as is known, has never been declined. The first 12 members included, in addition to generals and admirals, Lord Rutherford, winner of the Nobel Prize for chemistry; Sir William Bragg, the physicist; Sir James Jeans, astronomer and physicist; and Sir James Frazer, anthropologist. Musicians, painters, and writers were among later recipients, the last category including T. S. Eliot. Florence Nightingale was the only woman ever to have held the order.

MERIVALE, měr'ĭ-vāl, **Charles,** English historian and ecclesiastic: b. Barton Place, Devonshire, March 8, 1808; d. Ely, Cambridgeshire, Dec. 27, 1893. He was the son of John Herman Merivale (1779–1844), a barrister, translator, and minor poet. After graduating from St. John's College, Cambridge University, in 1826, he studied theology and was ordained in the Church of England in 1833. He was rector of Lawford, Essex, from 1848 to 1869, and during this period was chaplain to the speaker of the House of Commons. In 1869 he declined the professorship of modern history at Cambridge but became dean of Ely, in which capacity he served until his death. His *History of the Romans under the Empire,* 7 vols. (1850–1862), considered his greatest work, unduly glorified imperialism. *The Fall of the Roman Empire* (1853) was a popular epitome of a section of that work; and his *General History of Rome from the Beginning to the Fall of the Western Empire* (1875), was a summary of the entire work. His *Autobiography and Letters,* edited by his daughter, appeared in 1899.

MERIVALE, Herman Charles, English novelist: b. London, 1839; d. there, Jan. 15, 1906. He

was educated at Harrow and Oxford, became a barrister of the Inner Temple in 1864 and edited the 'Annual Register' 1870–80. Among his publications are 'The White Pilgrim and Other Poems' (1875); 'The Cynic' (1882); several plays; 'The Whip Hand' (1884); 'The Dove' (1888). He was a son of J. H. Merivale.

MERIWETHER, Lee, American lawyer, social reformer and author; b. Columbus, Miss., 25 Dec. 1862. Having obtained a secondary education at Memphis, Tenn., he there published the *Free Trader* with a brother, Avery, in 1881–83, and in 1885–86 toured Europe afoot from Gibraltar to the Bosporus for study of the condition of Continental workingmen and of the protective tariff. In 1910, on the 25th anniversary of this "Tramp" trip through Europe, he covered the same route in an automobile; the contrast between walking and motoring abroad, and the changes that had taken place in the manners and customs of the peoples of Europe between 1885 and 1910 were interestingly set forth in a book entitled 'Seeing Europe By Automobile' (New York 1911). He was appointed by the Secretary of the Interior to write for the United States Labor Bureau a report on the 'Condition of European Labor,' published in the annual report of the bureau for 1886. In 1886–89 he was employed as a special agent of the Department of the Interior for which he made investigations of labor in the United States and the Hawaiian Islands, and in 1891 visited the island prisons of the Mediterranean. He was admitted to the bar in 1892, and in 1893 entered practice at Saint Louis. In 1889–90 and 1895–96 he was labor commissioner of Missouri. His reports on municipal government and street-railway franchises led to his nomination in 1897 for the mayoralty of Saint Louis on the Democratic ticket. He was defeated at that time and also in 1901, when he was candidate of the Public Ownership party. Besides his various reports, he has published 'A Tramp Trip: How to See Europe on Fifty Cents a Day' (1887); 'The Tramp at Home' (1890); 'Afloat and Ashore on the Mediterranean' (1892); 'Miss Chunk' (1899); 'A Lord's Courtship' (1900); 'Seeing Europe by Automobile' (1911); 'War Diary of a Diplomat' (1919), etc.

MERLE D'AUBIGNÉ, Jean Henri. See D'Aubigné, Jean Henri Merle.

MERLIN, mêrlĭn, a semi-legendary British prophet and magician, supposed to have flourished toward the end of the 5th century. The accounts of him are hopelessly mixed with fiction. He was said to be the son of a demon and the daughter of a British prince, and was brought up at Caer-Merlin, a city supposed to be the modern Carmarthen. He received from his father the power of working miracles and was the greatest sage of his time, the counsellor and friend of English kings. Vortigen, according to the legend, on the advice of his magicians, had resolved to build an impregnable tower for security against the Saxons but the foundation was scarcely laid when the earth opened by night and swallowed it up. The magicians informed the king that to give firmness to the foundation he must wet it with the blood of a child born without a father. After much search the young Merlin was brought to the king. Merlin disputed with the magicians and showed them that under the foundation of the tower was a great lake, and under the lake two great raging dragons, one red, representing the British, one white, representing the Saxons. The earth was dug open, and the dragons began a furious battle; whereupon Merlin wept, and uttered prophecies respecting the future state of England. Merlin is a character in Tennyson's 'Idylls of the King.' A collection of the prophecies attributed to him appeared in Paris in 1498, at London in 1529 and 1533, at Venice, 1554. They can be traced back to about 1360. His prophecies were published at Edinburgh in 1615 and contain also those ascribed to the Cambrian or Welsh Merlin. Consult Child, 'Her Book of Merlin' (New York 1904); Tennyson, Alfred, 'Idylls of the King.'

MERLIN. This dramatic narrative poem by Edwin Arlington Robinson is among the most distinguished and significant products of recent American literature, and bids fair to take its place beside the best of its very admirable kind. It is entirely modern in its spirit and treatment, with lines like these that mark its date:

> "Time swings
> "A mighty scythe, and some day all your peace
> "Goes down before its edge like so much clover."

In Mr. Robinson's poem King Arthur and his knights are not romantic heroes, as other poets have made them, not "our conception of what knighthood should be"; they are a modern poet's conception of what leaders of men always and universally are,—king, warrior, lover, fool; Arthur, Gawaine, Lancelot, Dagonet. Nor is Mr. Robinson's Merlin like Tennyson's — a magician in his dotage falling a victim to the wiles of a false woman. He is a prophet whose "memories go forward"; he is a man "Who saw himself, A sight no other man has ever seen," and he follows Vivian, "a woman who is worth a grave," because Fate wills it so. It is not the age of chivalry but our own time, our own double world of hope and of reality, with its loves, faith, fears, wars and failures that Mr. Robinson revivifies in 'Merlin.' The philosophy of the poem, that faith and creative love will someday save the world, is a lustrous background for the story: "The torch of woman, who, together with the light That Galahad found, is yet to light the world." As a tale Merlin is vivid and compelling, with scenes, like that of Merlin's first meeting with Vivian and his final parting, which rival the best in drama for beauty and intensity.

Edith J. R. Isaacs.

MERLIN, or **STONE-FALCON,** a small and handsome European falcon (*Æsalon æsalon*) prevailingly blue, known throughout the temperate parts of the old world, and very similar to the American pigeon-hawk (q.v.). It is fierce and courageous, and is trained in falcony for the pursuit of the birds that form its natural prey.

MERMAID, a mythical being living within and under the sea, having the form of a woman above the waist and that of a fish below it. They are usually described as having great personal charms, and as using these for the purpose of luring imaginative and amorous men to

destruction by enticing them into the depths of the sea; and, as a correlative, they are sometimes represented as securing their own destruction by quitting the sea, through marriage with some favored human husband by which they magically obtain temporarily a complete human form and soul, but always end in bringing disaster to one or both of the sacrilegious pair. Mermen are also occasionally heard of, but take an unimportant part in the legendary lore of the sea.

This mediaeval notion is doubtless a survival of the primitive fancies, half fearful, half poetic, which created the classic conceptions of tritons, nereids, and the like. Shakespeare wrote (*Antony and Cleopatra,* II, 2, 211):

"Her gentlewomen, like the Nereides,
So many mermaids, tended her."

All of these ideas probably arose from a mixture of observed human resemblances in certain marine animals with purely mystical fancies which peopled the ocean with similitudes of terrestrial creatures. Primitive men have everywhere derived a large part of their sustenance from the natural products of the waters; and always the vastness and mystery of the sea, full of strange creatures and incomprehensible phenomena, have powerfully affected the imagination of the ignorant and superstitious. So this day the ocean is more familiar and more important in the life of many isolated peoples, who dwell upon its margin and derive their support almost exclusively from it, than is the land; and they invest it and everything it contains with a wondering regard which the inlander can neither share nor understand. To these, even in civilized regions (as on the coast of Ireland or the Hebrides), mermaids remain only one of many present realities, herding sea-cattle and piping in wait for unwary humanity as surely as when seahorses raced over the Aegean waves with the scar of Poseidon or the Sirens tempted the mariners of ancient Greece. In one form or another such stories have been rife in the folklore of all maritime peoples since prehistoric times; and, although not so widespread, the belief in mermaids, and their kith and kin, is still a matter of firm faith with hosts of persons in all parts of the world. Folklore abounds in evidence of this.

The physical basis for these notions rests upon the resemblance which some marine animals bear to human beings when seen at a distance and in certain attitudes. Such, in northern countries, are various seals, which formerly abounded upon the coasts of western Europe, and still are to be seen in the less frequented spots. They have a way of lifting their round heads and shoulders from the water, with a queer human intelligent look upon their faces, and hugging their young to their bosoms with motherly affection. Impressed with this resemblance, easily turned into a story to beguile a long winter evening or to amuse a child, and growing with imaginative repetitions, the northern peoples were quick to believe the similar and more elaborate stories brought to them by early voyagers from the Mediterranean, and so the tales grew and changed into the rich folklore of the coasts of the North Sea.

The southern stories, embellished by classic culture into the sea-myths of Neptune, Proteus and the sea-nymphs of old, and descending into the mermaids and mermen of mediaeval folklore, yet alive around the Mediterranean and Oriental seas, and among sailors generally, probably have their root in the aspect of the East Indian and African dugongs (q.v.). Near at hand these uncouth monsters would never be mistaken for human beings; but seen at a distance, by fearful and wondering voyagers along the coast, such an error might easily happen, for they frequently stand upright among the weedy shallows of the coasts, perhaps draped with loosened vegetation like long hair, and holding to their breasts a young one who nurses from pectoral mammae much as a human baby would do. Such reports, brought back to the inquiring poetic minds of Greece, might easily blossom into the tales of sea-mythology which formed so large and real a part of the popular belief as well as of the legendary lore of the classic age of India, Persia and the Mediterranean peoples. The fish-gods of the Phoenicians and other idolaters are closely related.

From this has come down to us the extensive and varied use of mermaids and mermen in heraldry. "In French heraldry," says Robinson, "the mermaid is called the Siren; in German she has two tails; in the Italian she carries a harp; and in many cases in each country she is crowned. In England it is a very ancient crest, and among others the lords Byron, the earls of Portsmouth . . . and many others display the sea-maiden in their armorial bearing. With her comb and Looking-glass she smiles at us from the shields of the Holmes, Ellises, Lapps; and as a supporter holds up the arms of the Viscounts Boyne and Hood, the earls of Howth and Caledon, and is borne by the heads of the families of Sinclair of Rosslyn, and Scott of Harden. Two mermaids crowned are the supporters of the Boston arms."

Artificial mermaids, claiming to be preserved realities, have formed a part of the stock of curiosities of wonder-shows since time immemorial; and most of those exhibited since the days of Barnum have been the products of Japanese ingenuity.

ERNEST INGERSOLL.

MERMAID'S HEAD, a globose sea urchin, as one of the heart urchins.

MERMAID'S PURSE, the egg case of the skate (or shark), which is often cast up empty on the shore.

MERMAN. See MERMAID.

MERO, or **MEROU,** a West Indian name for a jewfish (q.v.).

MEROBAUDES, Flavius, a Spanish rhetorician and poet of the first half of the 5th century A.D., eminent also as a general, has left us a short hymn in honor of Christ and fragments of five historical poems. L. Jeep in his edition of Claudian (Leipzig 1876–1879) publishes four of these poems.

MEROE, mĕr'ō-ē, ancient city and state of Ethiopia, in the northeastern part of Africa. The city is still represented by ruins and pyramids near Kabushia, on the Nile north of Khartum, and the state forms the district often spoken of as the Isle of Meroë, extending southeast to Abyssinia, and in the

northwest forming a part of Nubia. It was distinguished for its mineral and cereal wealth and at an early date was the centre of an active and varied commerce including the great caravan trade between Ethiopia, Egypt, Arabia, northern Africa and India. The government was in the hands of a caste of priests, who chose a king who was obliged to live and act according to certain prescribed rules. The priests could sentence the king to death in the name of the gods, and he was forced to submit. The priests were of a lighter complexion than the other inhabitants and may have come from India. Ergamenes, king of Meroë in the 3d century B.C., during the reign of Ptolemy II in Egypt, first made himself independent of this oppressive priesthood by murdering the priests in the golden temple. Meroë and Axum (in Abyssinia), which appears to have been a colony of Meroë, remained the centre of the southern commerce till the time of the Arabians. The existing monuments of their architecture, and many other vestiges, exhibit an advanced religious and social cultivation. The University of Liverpool in 1910–11 financed excavations here, interesting ruins were uncovered and many valued relics obtained. Consult Budge, 'The Egyptian Sudan' (London 1907).

MEROPE, the title of an Italian tragedy in blank verse by the Marquis Francisco Scipione Maffei (1675–1755), first performed at Modena in 1713. Appearing just after the dreary period of 17th century stagnation in Italian letters, it obtained a European reputation. More than 60 editions were published and it was widely translated. It attained in Italy an unprecedented success on the stage and is important also for its influence upon the development of the Italian theatre, whose standard Maffei raised perceptibly.

The subject of the play is taken from Greek mythology as related by Apollodoro (II, 8–5) and Pausanias (IV, 3–6). Merope is the queen of Messena whose husband, Cresfonte, and two children have been murdered by her brother-in-law, Polifonte, who then usurps the royal power and attempts to force the queen to marry him. On this tragic story Euripides wrote his 'Cresfonte,' which is not extant. Maffei was the first modern dramatist to handle the material and reveal its superb possibilities. He dispenses with the love element so prevalent at that time in the French theatre and proves that without it a play can retain the interest of the spectator. His idea is that such a play shall depict but a single passion, in this case a mother's love for her son. The scene (III, 4) in which Merope, believing that she has in her grasp her son's slayer, discovers in him her own son, the transition from anger and vengeance to surprise and then to the motherly love, is profoundly impressive. The dénouement, the death of the tyrant (V, 6), at the foot of the altar, is equally effective. Notable as are the tragedies of Voltaire and of Alfieri dealing with the same subject with the power characteristic of each of these master minds, nevertheless in intensity of plot interest and in dramatic treatment, Maffei's 'Merope' remains unsurpassed. Consult 'Opuscoli e lettere di Maffei' (Milan 1844), for the text and interesting material. A school edition, edited by A. C. Clapin was published in London in 1890. The text, with variations and introduction, appeared later in No. 108 of the 'Bibliotheca Romanica.'

JAMES GEDDES, JR.

MEROSTOMATA, a sub-class of arthropods, allied to the *Crustacea,* and represented by only a single survivor (the horsefoot crab), but including a large series of fossil forms which flourished in the Palæozoic Age from mid-Cambrian onward. They were somewhat scorpion-like in form, although sometimes of gigantic size, and ranked between the superior trilobites and inferior arachnids. The Merostomata are characterized by having six pairs of ambulatory limbs about the mouth, the first of which terminate in some, if not in all, cases in chiliceræ. The others serve as organs of locomotion, and their coxal joints for prehension and mastication. The prevailing opinion is that the body is divided into two parts (cephalothorax and abdomen) instead of three (headshield, thorax and abdomen) has been changed by recent discoveries that make the trilobate character of the structure indubitable, and establish a close relationship with the trilobites. The sub-class comprises three orders, *Xiphosura,* the horsefoot crabs (q.v.); several species of which still exist; the *Synxiphosura,* Silurian and Cambrian fossil forms; and *Eurypterida* (see EURYPTERUS). Consult Packard, 'Zoology' (1897), and Zittel-Eastman, 'Textbook of Paleontology' (Vol. 1, 1900), which contains an extensive bibliography.

MEROVINGIANS, mĕr-ō-vĭn'jĭ-ąnz, the first dynasty of Frankish kings which ruled in the northern part of Gaul, since called France. They derived their name from Merowig (Merovæus), the grandfather of Clovis. They ruled from 496 till 752, when they were supplanted by the Carlovingians. Pepin the Short caused the overthrow by deposing Childeric III, and sending him to a monastery. See FRANCE.

MERRELL, John Porter, American naval officer: b. Auburn, N. Y., 7 Sept. 1846; d. New London, Conn., 8 Dec. 1916. He was graduated at the United States Naval Academy in 1867, served with the European fleet 1867–70; was on signal duty on the Washington and Darien expedition of 1870–71, was in charge of the naval ordnance proving grounds 1877–79. He was also for a time an instructor at Annapolis and had command of the Atlantic fleet. He also did active work in the Department at Washington. He was retired by operation of law 7 Sept. 1908. In 1895–96 he was a member of the State Department Commission to investigate anti-foreign riots in the province of Szechuen, China.

MERRIAM, Augustus Chapman, American classical scholar: b. Locust Grove, N. Y., 1843; d. Athens, Greece, 1895. He was graduated at Columbia University in 1866 and after 1868 was connected with that institution successively as tutor, adjunct professor of Greek, and professor of Greek archæology and epigraphy. Dr. Merriam did much to promote the study of classical archæology in the United States. In 1887–88 he was director of the American School at Athens. He published 'The Phæacians of Homer' (1880); 'The Greek and Latin Inscriptions on the Obelisk Crab in Central Park' (1883); 'The Sixth and Seventh Books of Herodotus' (1885); 'The

Law Code of Gortyna in Crete (1886); *Telegraphy among the Ancients,* Papers of the Archaeological Institute of America, Classical Series 3 (Cambridge 1890).

MERRIAM, Clinton Hart, American naturalist: b. New York City, Dec. 5, 1855; d. Berkeley, Calif., March 19, 1942. He studied at Sheffield Scientific School, Yale University, during 1874–1877, and secured a medical degree at Columbia University in 1879. Thereafter he was in medical practice until 1885, when he was appointed chief of the United States Biological Survey. In 1910 he resigned this post to undertake biological and ethnological investigations under a trust fund established by Mrs. E. H. Harriman. For many years he participated in biological surveys in the United States and elsewhere, retiring in 1939. His numerous books included *Birds of Connecticut* (1877); *Mammals of the Adirondacks* (1882–1884); *Life Zones and Crop Zones of the United States* (1898); *Review of the Grizzly and Big Brown Bears of America* (1917); *The Buffalo in Northern California* (1926). He was the brother of Florence Augusta Bailey (q.v.).

MERRIAM, John Campbell, American paleontologist: b. Hopkinton, Iowa, Oct. 20, 1869; d. Oakland, Calif., Oct. 30, 1945. He graduated at Lenox College, Iowa, in 1887, and in 1893 he obtained a Ph.D. at the University of Munich. In 1894 he joined the faculty of the University of California, where he became professor of paleontology in 1905. He resigned this chair in 1920 to take the presidency of the Carnegie Institution of Washington, and he continued in this post until his retirement in 1938. He published many works on fossil reptiles, fossil mammals, and general historical geology, including *The Occurrence of Human Remains in California Caves* (1909); *The Emergence of Man* (1919); *Spiritual Values and the Constructive Life* (1933); *Science and Human Values: Time and Change in History* (1936).

MERRIAM, William Rush, American politician: b. Wadham's Mills, N. Y., July 26, 1849; d. Feb. 18, 1931. After graduating at Racine College, Wisconsin, in 1871, he entered the First National Bank of Saint Paul, Minn., becoming cashier in 1873. In 1880 he was elected president of the Merchants' National Bank, Saint Paul, and in 1882 he became a member of the Minnesota state legislature; he was chosen speaker in 1886. From 1889 until 1893 he served as governor of Minnesota; and from 1899 until 1903 he was director of the twelfth United States census.

MERRICK, Leonard, English novelist and playwright: b. London, Feb. 21, 1864; d. there, Aug. 7, 1939. After attending Brighton College he was employed for a time in South Africa and then went on the London stage, using the surname of Merrick in place of his family name of Miller; later he changed his name to Merrick by legal process. He turned to writing after two years as an actor, the first of his books to attain any measure of success being *The Man Who Was Good,* published in 1892. Numerous later novels included *Cynthia* (1897); *The Worldlings* (1900); *The Quaint Companions* (1903); *The Position of Peggy* (1911); *A Chair on the Boulevard* (1921); *The Little Dog Laughed* (1930). With collaborators, he also wrote five plays.

MERRILL, George Perkins, American geologist: b. Auburn, Me., May 31, 1854; d. Aug. 15, 1929. After graduating at the University of Maine in 1879 he became assistant in chemistry at Wesleyan University, Connecticut. In 1881 he joined the staff of the United States National Museum, and in 1887 became curator of the department of geology; from 1897 until his death he served as head curator of the department. During 1893–1915 he was also professor of geology and mineralogy at George Washington University. He did much pioneer research work on meteorites and the history of American physical geology, and developed the museum's geological and paleontological collections. His works included *Stones for Building and Decoration* (1891); *A Treatise on Rocks, Rock-weathering, and Soils* (1897); *The Non-Metallic Minerals* (1904); *The First One Hundred Years of American Geology* (1924).

MERRILL, Selah, American Congregational clergyman: b. Canton, Conn., May 2, 1837; d. Jan. 22, 1909. He studied at Yale Divinity School, and after ordination in 1864 he spent a year as chaplain of the 49th United States Colored Infantry. During 1874–1877 he was archaeologist of the American Palestine Exploration Society, and he served as United States consul in Jerusalem in 1882–1886, 1891–1894, and 1898–1907. He located the second wall of Jerusalem, outside of which Jesus was crucified. During 1907–1908 he was United States consul at Georgetown, British Guiana. His writings included *Galilee in the Time of Christ* (1881); *The Site of Calvary* (1885); *Ancient Jerusalem* (1905).

MERRILL, city, Wisconsin, seat of Lincoln County, on the Wisconsin River 15 miles north of Wausau; it is served by the Chicago, Milwaukee, St. Paul and Pacific Railroad. The city is located in an old lumbering region. There are manufactures of paper, doors and sash, shoes, dairy products, canned foods, and knit goods. Père René Menard, early French priest, had a mission here in 1661. The place was settled under another name in 1875 and was incorporated as a village in 1880; it took the name of Merrill when chartered as a city in 1883. It has government by mayor and council. Pop. (1950) 8,951.

MERRIMAC, The, a frigate of the United States Navy. See MONITOR AND MERRIMAC, THE.

MERRIMACK, river of the United States, formed by the junction of the Pemigewasset and Winnipesaukee rivers at Franklin, N. H. The Pemigewasset has its rise in the northern part of Grafton County, N. H., in the White Mountains; the Winnipesaukee is the outlet for the lake of the same name. The Merrimack flows nearly due south into Massachusetts when it turns, continuing its course east, then northeast into the Atlantic Ocean at Newburyport, Mass. The mouth of the river is a tidal estuary; the Merrimack is navigable for small vessels as far as Haverhill, Mass. A sand bar at the entrance to the river is constantly changing, proving a hindrance to navigation. The extensive water power of the Merrimack has been the main cause

of the development and prosperity of the entire region. Some of the country's cotton mills were erected on its banks, as well as woolen mills, carpet mills, and other manufactories. Besides Haverhill, other important towns on its banks in Massachusetts include Lawrence and Lowell; in New Hampshire, Nashua, Manchester, and Concord. The Merrimack has a length of 110 miles from the confluence of the Pemigewasset and Winnipesaukee to its mouth; the drainage area of the river covers 5,000 square miles.

MERRIMAN, Henry Seton. See SCOTT, HUGH STOWELL.

MERRIMAN, John Xavier, South African statesman: b. Street, Somersetshire, England, March 15, 1841; d. Aug. 2, 1926. He went to South Africa with his parents in 1849, and was educated at Rondebosch, near Capetown. In 1871 he was a diamond dealer in Kimberley, and during 1874–1875 he was a wine merchant in Capetown. Meanwhile he had entered political life in Cape Colony, and he became commissioner of public works during 1881–1884 and treasurer general in 1890–1893. A close friend of Prime Minister Cecil Rhodes, he headed the Cape parliamentary committee which inquired into the Jameson raid of 1895. During 1898–1900 he was again treasurer general, and in 1908 he became prime minister of Cape Colony. As leader of the South African Party (formerly the Afrikaner Bond) he took a prominent part in formulating the constitution for a united South Africa. He vacated the Cape premiership when the Union of South Africa was constituted in 1910, and thereafter was a staunch supporter of the Union government headed by Louis Botha.

MERRIMAN, Mansfield, American civil engineer: b. Southington, Conn., 1848; d. June 7, 1925. He graduated at the Sheffield Scientific School, Yale University, in 1871, and during 1873–1875 he was a member of the United States Corps of Engineers. In 1875 he returned to Yale as instructor in civil engineering, and in 1878 he was appointed professor of civil engineering at Lehigh University; he vacated this chair in 1907 in order to devote his time to consultation, mainly in hydraulics. For five years he was associated with the geodetic survey of Pennsylvania, having charge of primary triangulation. He also conducted research in the fields of hydraulics, strength of materials, and pure mathematics. His works included *Elements of the Method of Least Squares* (1877); *The Mechanics of Materials* (1885); *Strength of Materials* (1897); *Elements of Sanitary Engineering* (1898); *Elements of Hydraulics* (1912).

MERRITT, Anna Lea, American artist: b. Philadelphia, Pa., Sept. 13, 1844; d. April 7, 1930. She studied in Dresden, Germany, under Heinrich Hoffman, and in England under Henry Merritt, whom she married in 1877. Thereafter most of her life was spent in London. She exhibited at the Royal Academy, and her *Love Locked Out* was the first work by a woman artist to be purchased by the Tate Gallery, London. Other examples of her paintings included *Piping Shepherd* (in the Pennsylvania Academy of Fine Arts, Philadelphia), *A Scene on the Grand Canal,* and *Venice.* Her portrait of James Russell Lowell hangs in the Memorial Hall, Harvard University. She also took up etching, executing a portrait of Sir Gilbert Scott and two portraits of Mary Wollstonecraft. In 1879 she published *Henry Merritt's Art Criticism and Romance;* she also wrote *A Hamlet in Old Hampshire* (1902) and *An Artist's Garden* (1908).

MERRITT, Wesley, American army officer: b. New York City, June 16, 1834; d. Washington, D.C., Dec. 3, 1910. He graduated at West Point in 1860, and served through the American Civil War. In 1863 he was promoted brigadier general of volunteers, and the next year he became brigadier general. From the close of the war he was chiefly on frontier duty down to 1879, and during 1882–1887 he served as superintendent of West Point. In 1887 he became a brigadier general in the United States Army, and in 1895 he was promoted major general. As commander in chief of United States forces in the Philippines in 1898, he cooperated with Admiral George Dewey in the capture of the city of Manila. He was retired in 1900.

MERRITT, William Hamilton, Canadian mining engineer: b. Saint Catherines, Ontario, 1855; d. Toronto, 1918. He was educated at Upper Canada College, the Royal Military School, and the Royal School of Mines, London. After his return to Canada he practiced in Toronto as a mining engineer, and subsequently he lectured in mining engineering at the Kingston School of Mines. In 1885 he took part in the operations to suppress the rebellion in Manitoba of Louis Riel, and during 1899–1902 he served with the Canadian forces in the South African War. He contributed papers to numerous learned societies, and published *Economic Minerals of Ontario* (1896) and *Field Testing for Gold and Silver* (1900).

MERRITTON, town, Ontario, Canada, in Lincoln County on the Welland Ship Canal just south of Saint Catherines. Just to the east of the town, on June 24, 1813, the Battle of Beaver Dams was fought; 40 British soldiers and 200 Indians captured an American force totaling 650 men.

MERRY DEL VAL, mĕr'rē thĕl väl', **Rafael,** Roman Catholic prelate: b. London, England, Oct. 10, 1865; d. Rome, Italy, Feb. 26, 1930. His father was secretary to the Spanish legation in London. He accompanied his father to Rome when the latter was named Spanish ambassador to the Vatican, and in 1888 he was ordained in the priesthood. In 1892 he was appointed master of the robes and privy chamberlain to Leo XIII, and in 1897 he was papal delegate to Canada to investigate the question of separate Roman Catholic schools in Manitoba. He was consecrated titular archbishop of Nicaea in 1900, and in August 1903 he served as secretary of the conclave which elected Pope Pius X. In October of the latter year he succeeded Cardinal Mariano Rampolla as papal secretary of state, and he was created cardinal in November. From October 1914 until his death he was secretary of the congregation of the Holy Office. He wrote *The Truth of the Papal Claims* (1909).

MERRY WIVES OF WINDSOR, The, was Shakespeare's greatest prose play. It contains only about 15 per cent of verse lines, and

in the spirit of its scenes it is equally subdued, save for a flash of the old fire in the fairy poetry at the close. John Dennis and Nicholas Rowe report a story, current at the opening of the 18th century and inherently plausible, to the effect that this play was written within two weeks to the special order of Queen Elizabeth, who desired to see Sir John Falstaff in love. The wish is worthy of the queen's taste, and the manner in which it was satisfied indicates that Shakespeare did not work spontaneously. In point of time the play belongs with the greatest comedies—with *Much Ado About Nothing, Twelfth Night,* and *As You Like It.* It was licensed for publication in January 1602 and most likely composed shortly before, for it is hard to believe that the Falstaff of this play can have been created while recollection of the great Falstaff of *Henry IV* (1597, 1598) was very fresh in the author's mind. There is a radical difference between the two characters. In the *Merry Wives* Falstaff loses most of his peculiar wit and all the graver, pathetic side of his character. He loses his charm, not only for the spectator but for his companions. There is a sense of positive disaster in seeing the invincibly lovable knight of *Henry IV* and *Henry V* betrayed by his own creatures, Nym and Pistol, just as there is in hearing the Titanic liar of the Gadshill episode ignominiously relating to Brook-Ford the whole sorry truth of his discomfiture. "I do begin to perceive that I am made an ass," he is forced to say in the final scene, and Shakespeare must have felt as keenly as his readers the pity of thus reducing Falstaff to the level of Dogberry and Bottom. The play is brisk and entertaining, and is constructed with masterly technique, but it deals wholly with the externals of character and with unlikely incidents. Its type-figures—Slender, Sir Hugh Evans, Dr. Caius, the Host—when compared with Mercutio, Sir Toby, or the old Falstaff, are like pygmies after giants. There is no reason to believe that *The Merry Wives of Windsor* was regarded with special favor by the Elizabethans. After the Restoration it seems to have become one of the most popular of Shakespeare's comedies, though Samuel Pepys registers emphatic dissent when noting in his diary that on Aug. 15, 1667, he saw *The Merry Wives of Windsor,* "which did not please me at all, in no part of it." Precisely a century after its first publication, in 1702, a revised version by Dennis was brought out with the title, *The Comical Gallant, or The Amours of Sir John Falstaff.* Since the rise of the romantic movement, it has been one of the least liked of Shakespeare's comedies.

TUCKER BROOKE.

MERSEN, Treaty of, effected Aug. 8, 870, at Mersen (Meerssen), Netherlands, between Charles the Bald of France and his half brother Louis of Germany by which Lotharingia or Lorraine, the kingdom of their nephew Lothair II (d. 869), was divided between the east and west Frankish realms—France and Germany. From this date the history of the two national divisions and of the European state system begins.

MERSEY, mûr'zĭ, river in northwest England formed by the junction of the rivers Goyt and Etherow in Derbyshire. It flows northwest and west between Cheshire and Lancashire into the Irish Sea through a large estuary that forms the harbor of Liverpool. From the right it receives the Tame, at Stockport, and the Irwell; and on the left its chief tributaries are the Bollin and the Weaver. At Eastham, on the estuary, is the entrance to the Manchester Ship Canal, 35½ miles in length, through which large ocean steamers have direct access to Manchester. Beneath the bed of the river, extending from Birkenhead to Liverpool, are a railway tunnel (opened in 1886) and a road tunnel (completed in 1930). The length of the Mersey, including the estuary, is 70 miles.

MERSHON, mĕr-shŏn', **Ralph Davenport,** American electrical engineer and inventor: b. Zanesville, Ohio, July 14, 1868; d. Miami, Fla., Feb. 14, 1952. He graduated at Ohio State University in 1890, and the following year joined the staff of the Westinghouse Electric Company. Westinghouse transformers designed by him received an award at the Chicago Exposition in 1893. He retained his connection with the company, at Pittsburgh, Pa., and New York City until 1900, when he entered private practice as a consulting engineer. He designed and built several important high voltage transmission plants in Japan, South Africa, Canada, and various parts of the United States. His inventions included the six-phase rotary converter, a compounded rotary converter, a system of lightning protection for electrical apparatus, and a compensating voltmeter.

MERSIN, mĕr-sēn', or **ICEL,** ê-chĕl', seaport city, Turkey, seat of Içel vilayet, on the Mediterranean 40 miles west-southwest of Adana. Although the harbor is an open roadstead there is a considerable shipping trade. An American mission is located here. Pop. (1945) 33,148.

MERSON, mĕr-sôn', **Luc Olivier** (also LUC OLIVIER-MERSON), French painter: b. Paris, May 21, 1846; d. Nov. 14, 1920. His first picture exhibited in the Salon was *Leucothea and Anaxandros* (1867). In 1869 he carried off the Grand Prix de Rome, the supreme ambition of art students, by his painting *The Soldier of Marathon.* He produced the same year *Apollo the Destroyer,* now in the Museum of Castres. In 1872 he painted *The Martyrdom of Saint Edmund of England* (Museum of Troyes). Thereafter he devoted his pencil to the portrayal of legendary and mythological scenes and incidents. His chief works in this class are *The Vision, a Legend of the 14th Century* (1873); *A Patriot Sacrifice* (1874); *Saint Michael* (1875); *Saint Francis and the Wolf of Agubbio* (1878); *Saint Isidore* (a triptych) (1879); *The Judgment of Paris witnessed by Eros* (1884); *Mankind and Fortune* (1892); *The Annunciation* (1903). He also frescoed with scenes from the life of Louis IX the walls of the Saint Louis gallery in the Palais de Justice at Paris.

MERTHYR TYDFIL, mûr'thĕr tĭd'vĭl, county borough, Wales, in Glamorganshire 24 miles by rail northwest of Cardiff. From an unimportant village in 1780, it became a prosperous center of iron and steel manufacturing owing to its situation near the valuable coal and mineral fields of South Wales. The industrial depression after World War I seriously affected the borough. Richard Trevithick's steam locomotive, the first to be tried on rails, successfully hauled a train of 10 tons of iron and 70 men on

the Merthyr Tydfil-Pontypridd tramway in 1804. At the Dowlais iron works of Merthyr Tydfil, in 1856, Bessemer steel was first rolled into rails. The name of the borough is said to commemorate the martyrdom of Saint Tydfil, daughter of Brychan, who was put to death by the Saxons in the 5th century. Pop. (1951) 61,093.

MERTON, Walter de, English prelate: d. about Oct. 27, 1277. He served as chancellor of England during 1261–1263, and again in 1272–1274. In 1271 he was appointed justiciar, and from 1274 he was bishop of Rochester. He is best remembered as the founder of Merton College (q.v.).

MERTON COLLEGE. See OXFORD UNIVERSITY.

MERV, former name of the town of Mary, Turkmen Soviet Socialist Republic. See MARY.

MERWIN, Samuel, American author and editor: b. Evanston, Ill., Oct. 6, 1874; d. New York City, Oct. 17, 1936. He was educated at Northwestern University. In collaboration with Henry Kitchell Webster (q.v.), a friend from his boyhood days, he later wrote fiction about railroad-building in the United States, attaining some success with *The Short Line War* (1899) and *Calumet K* (1901). He also published in 1901 a novel entitled *The Road to Frontenac,* and this was followed by others which included *His Little World* (1903) and *The Merry Anne* (1904). From 1905 to 1909 he was associate editor of *Success Magazine,* and he was editor for the next two years. During 1907 he visited China to study the trade in opium, an account of which he gave in the book *Drugging a Nation* (1908). His subsequent novels included *The Trufflers* (1916); *The Passionate Pilgrim* (1919); *The Moment of Beauty* (1924); *Lady Can Do* (1929); *Bad Penny* (1933). He was a nephew of Frances Elizabeth Willard (q.v.), whose views on woman suffrage he espoused.

MERYON, mā-ryôn′, **Charles,** French etcher and engraver: b. Paris, Nov. 24, 1821; d. Charenton, Feb. 14, 1868. As a young man he served in the French Navy, which he was compelled to leave on account of ill health. Thereupon he turned to etching as a career, his chief works being picturesque spots in old Paris, many of which were subsequently destroyed. Between 1850 and 1854 he executed a series of 23 etchings known as *Eaux-fortes sur Paris,* by which he is best remembered. He met with little success, however, and lived in poverty until his mind failed and he was confined in a mental hospital, where he died.

MESA, mā′sà, city, Arizona, in Maricopa County 15 miles east of Phoenix; it is served by the Southern Pacific Railroad. Industrial activities are connected with the packing of vegetables and citrus fruits, and the ginning of cotton. The city was founded by Mormons in 1878. Government is by mayor and council. Pop. (1950) 16,790.

MESA, in geography, large, tabular, steep-sided blocks of land produced by the dissection of a plateau by the agency of rivers. The term is in common use in the great plateaus in the southwestern area of the United States. Smaller and less precipitous formations of the same type are frequently termed buttes.

MESA VERDE NATIONAL PARK, administered for the people of the United States by the National Park Service, a bureau of the Department of the Interior, is situated in southwestern Colorado. This area, comprising more than 51,000 acres, is a high tableland, rising abruptly from the floors of the Montezuma Valley on one side and the Mancos Valley on the other. Geologically it is the type locality of the Mesaverde formation of sandstones and shale that overlie the rocks of the Mancos formation, the whole exemplifying in striking scenic effects the forces of erosion which have worked upon the Rocky Mountain uplift. The surface of this mesa is broken by many canyons, the more rugged as they descend toward the Mancos. It is along these canyons, and in the great caverns of their sidewalls, with the overhanging rock serving as roofs, that the many hundreds of ancient villages of prehistoric Indians are found, to be visited yearly by an ever increasing number of tourists, and to be under constant study by those archaeologists whose patient research is slowly revealing the pattern of a fascinating phase of our pre-Columbian history.

Abandoned by the prehistoric people many centuries ago, and subject not only to the ravages of time but also to the unconscious vandalism of early plunderers, the cliff houses, pueblos, and pit houses are now given adequate federal protection. Visitors, though given every reasonable facility for enjoying the park, are required to observe the rules made necessary in pursuing the intent of the congressional organic act: the preservation of such park areas for the enjoyment and education of future generations. No cliff dwelling may be entered except in company of a park ranger. This rule does not apply to the ruins on the top of the mesa, which may be freely visited any time during the daylight hours by those who register at the park entrance or at the excellent Museum. For more than a thousand years sedentary Indians, unwarlike and mainly subsistent upon agriculture, lived in the Mesa Verde and surrounding regions. The discovery of the more important Mesa Verde pueblos was made in December 1888 by Richard Wetherell and Charles Mason, local cattlemen who were hunting stray stock on the mesa top. Later, Mason said "We had heard of Cliff Palace before we saw it. A Ute Indian named Acowitz had told us about it and we had always hoped to find it. The Utes were afraid of the ruins because of the spirits of the old people they believed to be there."

Beginning with a simple culture at about the opening of the Christian era, these people had reached by the end of the 13th century a high level that had even spread in some small degree to the wild tribes with whom they had contact. [The contact was not fortunate for the peaceable Pueblo people, as we shall see as we consider the four periods of progress that have been identified by the archaeologist.] Up to about the year 400 the outstanding craft of the Mesa Verde people was the weaving of baskets. They seem not to have had pottery, and their only missile weapon was the atlatl (throwing-stick). They lived in huts over shallow pits or in rough shelters on the floors of caves. Cooking, aside from

roasting over coals, was done by means of putting hot stones in their well-made baskets. In the floors of their cave houses they stored some of the products of their meager fields on the mesa. The years from about 400 to 700 are known as the Modified Basket Maker period. Here we begin to encounter pottery of a plain gray type that supplanted baskets for such use as cooking and water carrying. The folk either invented for themselves the bow and arrow, or received it from the outside. Most important, they built houses. These were only head-high roofs over shallow pits, but they were homes for single families, in a total population that seems to have greatly increased. Weaving was practiced, and the farming had become more important. Toward the end of this period the roofed pits gave way to rectangular rooms with vertical walls, and these, grouped together, formed large villages. What is known as the Developmental Pueblo Period occupied the years from about 700 to 1000 A.D. The villages became more compact. The "pueblo" (giving it the Spanish word for village) was about to come to the full fruition of the Classic and final period in the culture of these people. It was a time of eager experiment. Many kinds of house walls were tried—adobe, adobe and poles, combination of stones and adobe —until they finally arrived at coursed masonry of superior artisanship. In the cluster of houses around open courts were pit houses for ceremonial purposes, now called kivas. The pottery was not only greatly improved, but each area had its own definite type. Cotton was woven. A strange innovation appeared, whereby a cradle made of wood was adopted, which had the effect of deforming the heads of the infants, flattening them on the back of the skull. At this point of the cultural development of the Mesa Verde people, and probably just about as their great period was beginning, this nonwarlike prosperous folk had become targets for nomadic bandits. The cliff dwellings that attract most attention from the modern visitor thus came into being. (See CLIFF DWELLERS.) Clearly these cave pueblos, or cliff houses, were a defensive step. Such impressive structures as Cliff Palace, Square Tower House, Spruce Tree House, and Long House were the product of this flowering period. A rigid social structure, with a highly ritualized religious ceremony had evolved from the first rude social behavior and beliefs. Now the pottery was not only more efficient, but the artist in the potter was achieving animal figures and geometrical designs, the finest ware having black figures upon light gray. There was a profusion of jewelry of turquoise and other colored stones. However, the end of the pueblo life was now in sight. What the invasion of hostile tribes could not do, the phenomenon of a radical climatic change did. Beginning about 1276 and continuing for 24 consecutive years there was insufficient moisture to grow crops. The springs failed and the rivers ceased to flow. One by one the villages were abandoned. The pueblo people simply shouldered what belongings they could carry and moved on, perhaps to the southward and eastward.

FREEMAN TILDEN,
Author, "The National Parks."

MESCAL, měs-kăl′, a fiery liquor produced in Mexico from several species of agave. The most famous liquor, however, is made from the "hearts" of the species *Agave tequileana.* The city of Tequila, in the state of Jalisco, is the center of this particular industry. The Tequila agave resembles in the appearance of its stiff lancelike leaves the sisal hemp plant, though it sends out its leaves from a great bulb-like cellular mass which forms the heart of the plant. This heart, when denuded from its leaves and detached from the root, is cleft in two, and a dozen of these pieces make a fair load for a mule, for they must be transported from the fields where grown to the city, sometimes a journey of several miles. These hearts are roasted in pits, within the distillery enclosures, dug four or five feet deep and considerably wider. A hot fire is built of mesquite wood, and large stones distributed through the fuel. The "heads" are then heaped over the burning mass until a huge mound is formed, which is covered first with grass and then with earth, and the mass left several days to cook. When the mound is opened the raw product is found to have changed to a dull brown in color, and the juices to have been converted into sugar. White hot and steaming, the mass is taken to another pit, stone-paved, on the bottom of which revolves a heavy stone crusher, really an arrester operated by mule power. Here it is ground into pulp and the semi-liquid mass carried in deep trays on the heads of Indians to the vats where it remains to ferment. Then it goes to the rude stills, and is run off as mescal.

The commercial mescal is a colorless liquor sometimes with a slight amber tint, though much of it is like alcohol. Some of the higher grades are given fancy names which serve as trademarks. It is far too strong a liquor to be drunk with impunity, though its fiery quality seems to suit the Mexican taste for hot things. Zotol is another liquor, made in the same way from the bulblike heart of a species of *Dasylirion,* which is said to be as strong as 95 per cent alcohol. These liquors should not be confounded with aguardiente, which is made from sugar cane. The Mexican name means burning water.

MESDAG, Hendrik Willem, měs′dăĸ, Dutch marine painter: b. Groningen, Feb. 23, 1831; d. 1915. He was a banker, following in his father's footsteps, until his 36th year, when he devoted himself to art, studied under Alma-Tadema, who was a relative, and under Roelofs, and lived at The Hague, with a studio at Scheveningen. He took a foremost rank among modern painters of the sea, and conveyed the idea of water-masses and motions very felicitously. He presented his splendid collection of paintings and art objects to the nation. His pictures include *Fishing Boats at Scheveningen, Strand of Scheveningen, Morning on the Scheldt,* and *In Peril.*

MESENTERY, měs′ĕn-tĕr-ĭ, a double fold of the peritoneum which attaches the small intestine to the spinal column, but in such a manner as to permit great freedom of motion. The corresponding support of the large intestine is the mesocolon, with the mesorectum. The mesentery contains between its folds several blood-vessels, lacteals, lymphatics, nerves, and the ganglia called mesenteric glands, which are connected with the lymphatico-lacteal system.

It is about four inches wide, and extends nearly the whole length of the intestine. It is subject to several diseases, the most frequent of which is tubercular degeneration of some of its numerous glands. For this and other diseases of the mesentery, see PERITONITIS.

MESHA, king of Moab mentioned in II Kings iii, 2–27. This monarch threw off the yoke of Israel, then ruled by Ahab and the latter's sons, Ahaziah and Jehoram. Later Jehoram, with the aid of the kings of Judah and Edom, defeated Mesha and his hosts. Mesha was defeated and besieged in Kir-hareseth, but managed to hold out against his enemies although his country was overrun. See MOABITE STONE.

MESHED, mĕsh'ĕd, or **MESHHED,** mĕsh'-hĕd, Persia, capital of the province of Khorasan, in an extensive valley 500 miles northeast of Ispahan. It is surrounded by walls, and has many ruined houses, but its principal street is spacious and handsome, having a water-course, the banks of which are shaded by trees, passing through it, while at its extremity are seen the splendid cupola and gilded minarets of the mosque containing the shrine of Iman Riza, the son of Ali, the founder of the Shiites. This tomb has a gorgeous interior, a vast hall, like the central nave of a cathedral, rising loftily into a central dome ornamented with the richest colors and a profusion of gilding. This shrine attracts a vast number of pilgrims. Here also is the mosque of Gohur Shah, considered one of the most beautiful and splendid in Persia. The chief manufactures are velvets, sword-blades and some silk and cotton goods. A considerable number of the inhabitants are employed in cutting the turquoises obtained in the vicinity. The situation of Meshed on several great caravan routes makes it an important entrepôt for the produce of surrounding countries. The customs receipts for the territory approximated $250,000 annually up to 1914, were much lower during the World War, but have increased since. Pop. about 85,000.

MESHTROVITCH, Ivan, Jugoslav sculptor: b. Otavice, Northern Dalmatia, 1883, the son of a Croat. He was educated at the Vienna Academy of Arts and first exhibited his work in that city in 1902, and in 1911 his studies for the Serbian National Temple at Kossovo were shown in Rome. An artist of the highest type, endowed with astonishing ability, he is regarded in Europe — especially in England — as one of the greatest sculptors that ever lived. In 1915 a representative committee brought him to London and organized an exhibition of his works at the Victoria and Albert Museum. Art, political idealism, mythology and religious mysticism are inseparably bound up in his creations. His remarkable talent is expressed in the eclectic variety of styles of which he is master; it would seem that all known styles culminate in Meshtrovitch: Egyptian, Greek, Baroque, Byzantine, Assyrian and the most violently realistic modernism. Consult 'Ivan Meštrovič: A Monograph' (London 1919), by Sir John Lavery, Dr. Seton-Watson and others, with 68 photographic plates.

MESMER, Friedrich (or **Franz**) **Anton,** frēd'riç än'tōn mĕs'mĕr, German physician: b. Itzmang, near Constance, Baden, 23 May 1733; d. Meersburg, Baden, 5 March 1815. He was educated in medicine by Van Swieten and De Haen of the University of Vienna, made some study of astrology, came to believe in the influence of the stars, and attributed this supposed influence to magnetism. Having at first believed in the cure of diseased bodies by the use of magnets, he came wholly to discard the magnets and declared that an occult force, which he called animal magnetism, pervading the universe, resided in himself and afforded him an influence over others. In 1778 he went to Paris and set the town astir. He had undoubtedly an honest belief in the efficacy of his discoveries; but he took advantage of popular interest to enshroud his methods with mystery. Finally the government appointed a committee of noted physicians and members of the Academy of Sciences, including Benjamin Franklin, to investigate the matter; and the committee in a report, admitting many facts but attributing them to physiological causes and not to any such supposed agency as animal magnetism, so discredited Mesmer that he went to London, and later to Germany. The name mesmerism was formerly applied to the entire class of phenomena now known as hypnotism (q.v.). It is now claimed that there is a force in the human body generally called magnetiscor, which is under the control of the human will, and that when the control of this force passes to another hypnotism occurs. Among his writings are 'Mémoires sur la Découverte du Magnétisme Animal' (1779); 'Histoire Abrégée du Magnétisme Animal' (1783); and the 'Mémoire de F. A. Mesmer sur ses Découvertes' (1799). See HYPNOTISM.

MESMERISM. See HYPNOTISM.

MESNE (mēn) **PROCESS,** *in law,* an intermediate process which issues pending the suit upon some collateral interlocutory matter. Sometimes it is put in contradistinction to primary and final process, or process of execution, and then it signifies all such processes as intervene between the beginning and end of a suit.

MESODERM. See ANATOMY, COMPARATIVE; EMBRYOLOGY.

MESOHIPPUS. See HORSE, EVOLUTION OF THE.

MESONERO ROMANOS, mā-sō-nā'rō rō-mä'nōs, **Ramon,** Spanish writer: b. Madrid, 1803; d. 1882. After a short time spent in mercantile life he turned to journalism, and after some time spent on the Madrid *Press* he founded the *Semanario Pintoresco Español* which he continued to edit and manage until 1842. Mesonero was a great lover of his native city which, in his youth, was still the old-fashioned Spanish capital teeming with true native life, before it had begun to reflect the fashions, customs and manners of Paris. He rubbed elbows with his fellow city-dwellers everywhere and on every occasion; and out of this intimacy sprang interesting and well-written sketches of popular types, manners and customs. His comprehensive knowledge of his native city appears in 'Manual de Madrid'; 'Escenas Matritenses' (2 vols., 1836); 'Memorias de un setentón' (1880), and 'El Antigno Madrid.' Mesonero is one of the masters of modern Spanish. His language is ever graceful, tending to a slight diffuseness; but always preserving its purity and idiomatic

complexion and force. A collected edition of his works was published in Madrid in 1881 under the title 'Obras completas de Ramón Mesonero Romanos.' In 1903–05 two volumes more of his hitherto unpublished writings also appeared in Madrid. Consult for biographical sketch, Northup, G. T., 'Selections from Mesonero Romanos' (New York 1913).

MESONYCHIDÆ, a family of Creodonts, prevailingly North American, which were more highly specialized than any other. They acquired a wolf-like form, with a very long slender tail, and legs and feet digitigrade gait indicating powers of speed beyond those of any other creodont. Their heads, however, were disproportionately large and bear-like. The general structure, nevertheless, shows that they could not have been rapid and aggressive in their habits, and their teeth suggest that they lived principally on vegetable diet. Their development into hyenalike creatures may be traced to nearly the close of the Eocene.

MESONYX, a primitive carnivorous animal of the group *Creodonta* (q.v.), which must have resembled in external aspects, when alive, the modern Tasmanian wolf of Australia. Its remains are found fossil in the fresh-water formations of Eocene Age along the eastern base of the Rocky Mountains, and a complete skeleton is mounted in the museum of Princeton University, and a restoration is exhibited in the American Museum of Natural History in New York. This specimen (*Mesonyx obtusidens*) indicates an animal as large as a Saint Bernard dog, with its hindquarters drooped somewhat, like those of a hyena and a very long, slender tail. It is the type of a large family (*Mesonychidæ*) of wolf-like beasts widely distributed in Eocene time. Consult Woodward, 'Vertebrate Palæontology' (London 1898); Osborn, 'Age of Mammals' (New York 1910).

MESOPHYTE (Gr. "mid-grower"), *in botany and forestry,* a term used of plants which grow naturally in soil of moderate moisture. Thus the term is contrasted on the one hand with xerophyte, "dry-grower," and hydrophyte, "wet-grower," these latter terms being applied to plants requiring very little or very much moisture. Since soil of moderate moisture varies from moist to dry, whereas both the dryer and wetter soils are comparatively invariable in this respect, it naturally follows that Mesophytic plants show more adaptability to conditions of moisture than either hydrophytes or xerophytes. For the same reason, no doubt, the mesophytic flora, being comparatively stronger, is denser and marked by much wider variations of species, than the scanty and monotonous growths of poorer, because of wetter or dryer, soils.

MESOPOTAMIA or **IRAQ,** an independent state under a mandatory power, comprising the territory lying between the Euphrates and Tigris in Western Asia. The Arabs call those rivers El-Frat and Shatt respectively; the latter is also called Ed-Dijleh in its lower course. This region, extending from Arabia to Persia, was formerly included in the Ottoman empire. Its independence was recognized in the treaty of peace with Turkey, after the World War, and it was placed under mandate to Great Britain. A council of state was formed in 1920 and administered the country under the mandate provisions. On 23 Aug. 1921 the British High Commissioner proclaimed the Emir Faisal King of the Iraq, 96 per cent of the populace having voted for him. The territory is divided into the vilayets of Mosul, 35,130 square miles, Bagdad, 54,540 square miles; and Basra, 53,580 square miles; total, 143,250 square miles. The population of Mesopotamia, or Iraq, according to the census of 1932, was 2,857,077—Bagdad, 1,362,800; Basra, 789,800, and Mosul, 704,688. The country to which the name properly applies as extending between the two rivers has a gradual fall of nearly 1,000 feet from the spurs of the Taurus range to an old coastline south of Hit, whence an almost unbroken plain stretches to the Persian Gulf. The natives give the name of El Jezireh (the island) to the upper or northwestern portion, and that of Irâk Arabi (the ancient Babylon) to the lower or southeastern section. This latter, indeed, is often excluded as being beyond the confines of Mesopotamia proper. Low ranges of hills break the great plain of Upper Mesopotamia; between them the Khabur and its tributaries flow to the Euphrates, through a desolate region that was once thickly populated. The mountain district bordering the plain and stretching to the Persian frontier forms part of "Kurdistan," a mere name that has no concrete geographical existence, being mostly comprised in the vilayet of Diarbekr and belonging mainly to Mesopotamia. Ethnically it includes the Kurdish and the Arab nomad tribes — respectively of Iranian and Semitic stock. Upper Mesopotamia is rich in grain, wine and pasturage; the lower is flat, dry and unfruitful. Between the Khabur and the Euphrates lies the Biblical *Aram-Naharaim,* or Syria of the Two Waters, also called *Padan-Aram,* or Syria of the Plain. It is mentioned in the Old Testament in connection with Isaac and Jacob (Gen. 24 and 27). The Greek title was probably not in use till after Alexander the Great invaded the East. The soil consists of a sandy clay of excellent agricultural properties; only where water fails is it incapable of cultivation. Its remarkable fertility is shown by the fact that it still remains unexhausted after having supported through many centuries the Assyrian, Babylonian and Persian empires. The number and vastness of the ruins that lie scattered over this region from Babylon to Nineveh still bear silent testimony to its former flourishing condition. Since the cuneiform inscriptions gathered from these ruins have yielded up their secret to the researches of modern science, we have learnt with certainty that the plains of Mesopotamia were the scenes of successive civilizations, rivaled in splendor and antiquity only by those of ancient Egypt. To-day, in certain localities, may be found lions, leopards, wild asses, boars and gazelles.

Mesopotamia is essentially a land of origins; so far as we know it cradled the human race and nurtured it for centuries until a new era was introduced by the Flood incidents, which are recorded not only in the Hebrew Scriptures, but also in the cuneiform inscriptions. Its early history is one of constant struggles for supremacy between contending nations. Mesopotamia and its adjacent plains have been associated with some of the most important turning-points of human history; for milleniums

these lands contained the capitals of great world-empires and have been closely connected with the most thrilling epochs of history. Even in the World War of 1914–18, Mesopotamia — by reason of the Bagdad Railway schemes — played a rôle the importance of which is as yet but inadequately recognized, for that railroad was the keystone in the German aspirations toward a world-empire. The Mesopotamians sprang from the Chaldæans, the primitive inhabitants; from the Cushites, who in the reign of Nimrod built the cities of Edessa and Nisibis; and from the descendants of Shem, of the tribe of Thara. The Hebrew race took its rise from this land when Abraham came from Ur of the Chaldees and settled in Canaan. It was also in this plain of Shinar that the confusion of tongues occurred. Babylonia was the mother of astronomy, and the 12 divisions on the dials of our clocks originated there, while the influence of Hammurabi's famous laws has penetrated down the ages into the legal codes of modern times through the intricate systems of Greek and Roman legislators. Mesopotamia was originally a part of Nimrod's dominions, the founder of Calneh or Nippur. After an interval of more than 700 years (2000 B.C.) Cushan Rishathaim reigned in Mesopotamia, who extended his territory over the Euphrates. The Israelites, who then possessed Palestine, were compelled to pay him tribute for the space of eight years. In the Golden Age of the Assyrian power (790 B.C.) Mesopotamia was entirely subjected to that empire, and suffered the fate of its subsequent conquerors. Trajan brought it under Roman dominion in 106 A.D., but the Persians did not permit the Romans to remain long in undisturbed possession, for it was a constant cause of war between the Roman and Persian empires, and at last Jovian surrendered it to the Persians in 363 A.D. When the Arabs in 651 established a new empire upon the ruins of the Sassanide kingdom, Mesopotamia was also obliged to submit to the storm. In 1040 it fell into the hands of the Seljuks. From that time it had many rulers in rapid succession. Genghiz Khan made himself master of it in 1218, but in 1360 it fell into the hands of Tur Ali Bey. Timur conquered it 40 years later, and in 1514 it was incorporated in the Persian Empire under Ismael Sophi. In 1554, however, the Persians were compelled to surrender more than half of it to the Turks; and though they again recovered the lost portion in 1613, they were unable to withstand the attacks of Amurath IV, who united this in 1637, with many other provinces, to his empire. Despite its vicissitudes and the wars fought on its soil, the country remained rich and prosperous until the battle of Kadisia (635 A.D.) placed it at the mercy of the Arabs. Assyria and Babylonia were the wealthiest countries of antiquity, and Mesopotamia was the richest part of the great Persian Empire. In olden times Babylonia was perfectly irrigated, but the wonderful system of canals fell into ruins under the Turks. As the nomads pressed forward the peasants were driven from their lands, and the great irrigation works were neglected, and the Euphrates, no longer controlled, spread out into wide fever-bearing marshes. The work of devastation commenced by the Arabs was completed by the Tartars, Mongols and Turks, with the result that one of the most fertile regions in the world became practically a desert abandoned to nomads. Arabs now form the majority of the population, though the original inhabitants are still represented by Kurds, Yezidis or "devil worshipers," Nestorians, Chaldæans or Roman Catholic Aramœans and Jacobites in the north; and by Salians in the south. There are about 80,000 Arabic-speaking Jews resident in Mesopotamia who guard with reverence the traditional tombs of Joshua near Bagdad, of the prophet Ezekiel near the banks of the Euphrates, and of Ezra the Scribe on the Tigris near Kurnah. Besides its wealth of biblical associations, Mesopotamia is a land of sacred memories to hundreds of millions of Mohammedans. Two gilded domes on the splendid mosque at Kazmain cover the tombs of eminent teachers; this and the mosque at Samarra are Shiah shrines. A mile away, on the left bank of the Tigris, is the stately Hanifi mosque of the Sunnis at Muaththam, and the famous mosque of Abd ul Kadir is in Bagdad. The tomb of Mohammed's barber, Salman Pâk, is near the ruined arch of Ctesiphon. The holy Mohammedan cities of Kerbela and Nejif are near the banks of the Euphrates, to which thousands of embalmed corpses are brought by pilgrims every year from India and Persia for interment. Under the blighting misrule of the Turk Mesopotamia became one of the most desolate countries on earth, swarming with vermin and insects. What little manufacture is carried on is used for home consumption. Sugar, cloth, coffee, iron, indigo and copper are imported; the chief exports are dates, wool, cereals, gum, rice and hides. The foreign trade is mainly with Great Britain, India and Persia. From ancient times the country has been noted for its oil springs. The wells at Kirkuk and Jibbeh and others have been producing oil for centuries. The modern fields are on the Persian Gulf and in the Mosul region. Steamers can navigate the Euphrates as far up as Meskineh. The principal towns are Diarbekr, Urfa (Edessa), Harran, Mosûl and Bagdad. Basra, on the Shatt el-Arab (the confluence of the Tigris and Euphrates from Kurna) is the port of transhipment from river to ocean craft. The standard of education in Iraq is being steadily raised and public interest is increasing. In 1922 the foundation stone of the future Bagdad University was laid and construction was begun.

Mesopotamia and the War.— It has already been mentioned that Mesopotamia was the keystone of the Pan-German scheme by reason of the Bagdad Railway. According to German authorities on the subject, there were three alternative plans to promote the expansion of Germany into a great world-empire. In the early stages of the Pan-German movement, the vision of its advocates was fixed upon South America as the most promising territory upon which a Greater Germany might be built. Here, however, the Monroe Doctrine stood in the way. The British Empire, as the largest landholder in the world, then became the focus of the Pan-Germanists, and here, again, a formidable barrier stood in the path — the British navy. Two avenues being thus barred by obstacles which could only be removed by an overwhelmingly powerful fleet, a third plan presented itself, a plan which provided for an

overland expansion where no Monroe Doctrine existed and no British navy could intervene. The scheme was to gain control of the Balkan peninsula by the elimination of Serbia, the only hostile barrier separating the Central Powers from a friendly power, Bulgaria. This accomplished, the road lay open to Constantinople, a junction which, in its turn, opened the door to Asia, via the Persian Gulf; to East Africa and Australia. The principal artery of communication lay in Mesopotamia — the Bagdad Railway. It was calculated that this project could be carried out without coming into physical contact with either British territory or navy, and would place Germany in a position eventually to strike both at India and Egypt, a variation of Napoleon's plan of campaign for breaking the power of Britain. According to Prince Bülow, former German chancellor, this undertaking "threw open to German influence and German enterprise a field of activity between the Mediterranean Sea and the Persian Gulf, on the rivers Euphrates and Tigris, and along their banks. If one can speak of boundless prospects anywhere, it is in Mesopotamia" ('Imperial Germany,' p. 116). These words were no exaggeration, for Sir William Willcocks, an English engineer who had surveyed the country and planned a gigantic system of irrigation, part of which he had carried out before the war, had said, in 1903, that "Of all the regions of the earth, no region is more favored by nature for the production of cereals than the lands on the Tigris." This authority stated that the irrigable area of Mesopotamia was from two to three times as large as that of Egypt, which leads to the presumption that the country could support some 30,000,000 people. Persia and Turkey being decrepit and moribund states, the Pan-Germanists saw in Mesopotamia a field for exploitation which would make it for Germany what Egypt was to Great Britain or Morocco to France. German professors had painted the possibilities of this region to enthusiastic audiences in glowing colors, and had not omitted to point out that a German foothold on the Persian Gulf would imperil the position of Great Britain in India and Egypt. Now the most important route of the British Empire is the sea-route from England to India and Australia via the Suez Canal. The value of the Persian Gulf as a strategical British position has been pointed out by Admiral Mahan, on account of the Red Sea being merely a continuation of the Suez Canal, both of which could be dominated by a hostile power holding the gulf. The British, however, have not awakened to the importance of the gulf only in recent years, for already in the days of Queen Elizabeth it was visited by English vessels; before ever the Turkish crescent appeared on the shore of Arabia the English flag was known and respected in the Persian Gulf. The East India Company planted a depôt at Bandar Abbas in its early days and for nearly two centuries fought with Dutch and Portuguese rivals. The Anglo-Indian navy first surveyed the gulf and provided for its lighting to guide navigation. For 50 years the British hunted the pirates in the gulf and destroyed their strongholds. Altogether, for 300 years the British have been the guardians of the gulf, by protecting Persia, suppressing gun-running and slavery, fighting the plague and introducing the elements of sanitation among the natives on the coastline. All that Great Britain took in return was a spot on an island for a telegraph station; but she allowed no compromise on one point — that no power should be permitted to seize territory and no other flag should dominate those waters: The future of India and of the empire was bound up with British prestige in the Persian Gulf. These considerations explain the suspicion and mistrust of Great Britain regarding the absorption of Mesopotamia by Germany — an avowedly hostile power. In 1899 a German company obtained a concession from the Sultan to build a railroad from Konieh — the terminal of the Anatolian Railway — to Bagdad and Basra on the Persian Gulf, and from that year dates the German penetration of Mesopotamia. On realizing the political objects underlying the scheme, Great Britain protested and a diplomatic conflict began which was still in progress when the war broke out. During 1913–14 a strange medley of diplomatic negotiations were being held on the question of Mesopotamia and the railway, in which England, France, Russia, Germany and Turkey were involved, with the result that Germany obtained the acquiescence of the powers to be the sole *concessionnaire* of the railroad, though England forced Germany and Turkey to fix the terminal well inland at Basra. The lighting, marking and policing of the gulf by England was confirmed by Turkey. Meanwhile, Russian diplomacy had succeeded in creating intangible "spheres of influence" in Turkish territory by which the German railroad through Mesopotamia was hemmed in on either side, while Great Britain held the key of the exit. As compensation for being restricted at that exit, Germany received a concession to build a line from the Bagdad Railway to Alexandretta on the Mediterranean. At a later date Great Britain was apparently willing to grant an extension of the German sphere, for Prince Lichnowsky (q.v.) records in his famous Memorandum that "the greatest concession Sir Edward Grey made to me personally was the continuation of the line to Basra. We had not insisted on this terminus in order to establish connection with Alexandretta. Hitherto Bagdad had been the terminus of the line. In April 1941 the Regent of Iraq, Prince Abdul Illah was deposed following a coup d'etat by Rashid Ali al-Gailani, a pro-Nazi. The latter started an undeclared war against the British who landed forces at Basra on 19 April. Iraqi forces attacked the British airdrome at Habbaniyeh near Bagdad but were repulsed with severe losses. Nazi aid arrived soon after via Syrian airfields and the conflict became largely one of air battles between the Nazis and the R.A.F. On 24 May 1941 it was reported that the regent Prince Abdul Illah had returned to Iraq and was setting up a new administration. For details of the fighting see WAR, EUROPEAN, 1939—Vol. 28, p. 782.

MESOZOIC ERA, *in geology,* the mid-period of life in geologic time, also called the Secondary Period. Paleozoic precedes and Cenozoic follows this era, these two terms referring respectively to "older" and "newer," or "earlier" and "later," forms of prehistoric life. The subdivisions of the Mesozoic are the Triassic, Jurassic and Cretaceous periods (qq.v.).

The Life of the Mesozoic.—The life history of the era can be best understood, by first referring to the life of the Paleozoic (q.v.). That era was closed under conditions (aridity, glaciation and mountain making) unfavorable to plant and animal life, and as a result many unfit genera failed to live from Paleozoic on into Mesozoic. The long-hinged brachiopods, so characteristic of the earlier era, became extinct early in the latter. A few of the more primitive types persisted, but brachiopods became relatively unimportant. The old straight cephalopods practically became extinct with the passing of the Paleozoic. The nautilus type lived on through, even to the present time, but the era was characterized particularly by the dominance of a type called the ammonites, which appeared in late Paleozoic and died out at the close of the Cretaceous. They evolved rapidly and are valuable time markers. The Mesozoic has often been called the age of reptiles. This group of vertebrates, which appeared toward the close of the Paleozoic, in primitive form, developed rapidly into a number of highly specialized types. The Dinosaurs (terrible reptiles) developed along several lines. The carnivorous group walked on two legs, the two front limbs being very short. It was this reptile that made the famous three-toed tracks of the Connecticut Valley. Some of these Dinosaurs got to be as long as 40 feet. Herbivorous types also developed, great awkward beasts, some of them 80 feet long, 16 feet high and weighing probably 30 tons or more. This type were the largest land animals that ever lived. Late in the era peculiar armored Dinosaurs also appeared, with great horns on their heads and spikes on their tails. The Ichthyosaurs (fish reptiles) took to the sea and developed fins, much after the manner of modern fish. The Pterosaur (wing reptiles) developed the power of flight, some of them having a wing spread of 20 feet. These unusual reptiles all died off suddenly at the close of the Cretaceous, and in the following era reptiles took on a modern aspect. Peculiar birds with teeth, the first known representatives of the feathered world, are found fossil in Jurassic and Cretaceous rocks. A few primitive mammals, mostly of very small size, are known in the Mesozoic, but the group did not develop rapidly until after the close of this era. Among plants, the common groups of flowering plants did not appear until Cretaceous times.

Paleogeography of the Mesozoic in United States.— During Triassic and Jurassic times practically all of the United States east of the Mississippi was land. During Cretaceous the sea encroached on the coastal plain but did not reach the eastern interior region. The history of the west was more complex. During the Triassic a considerable part of the Pacific Coast region was under water but most of the interior was land. Similar conditions prevailed during early Jurassic, but late in the period a great arm of the sea encroached from the Arctic, reaching as far south as northern Colorado. The great differences in fossils seem to indicate that this bay was not connected with the Pacific directly. This arm of the sea withdrew before the end of the period which was marked in California and Oregon by great folding and intrusions of igneous rocks, making the mountain ranges known as the Sierra Nevada and Cascades. In the west the Upper Cretaceous was marked by a great inland sea, over the site of the Great Plains and Rocky Mountains, reaching from the Gulf of Mexico to the Arctic Ocean. Toward the close of the period this sea retreated, leaving great swamps in which coal was formed. The Era was brought to a close by a great period of folding known as the Lanamide Revolution which uplifted the Rocky Mountain Range.

MESQUITA, mās-kē'tä, **Salvador de,** Brazilian poet: b. Rio de Janeiro, 1646; d. Rome, in the early 18th century. He went to Rome, where he entered holy orders and was well known for his Latin scholarship. His 'Sacrificium Jephthæ' (1680), a sacred drama, established his poetic fame among contemporaries. His tragedies from profane history, 'Demetrius,' 'Perseus' and 'Prasias Bithyni,' all appearing at Rome between 1690 and 1700, also had once high rank.

MESQUITE, a tree or shrub (*Prosopis glandulosa* and *P. juliflora*) of the family *Mimosaceæ.* Several species of mesquite are very common in the southwestern United States from Texas to California, extending southward through Mexico and tropical America. In the United States they are usually shrubs, but farther south large trees. The branches are armed with spine, the leaves compound, of numerous leaflets, the flowers small and greenish, in spikes, and the fruit of long indehiscent pods. In the arid southwest the mesquite is often the only source of firewood, which is not obtained from the branches, but from the very large roots. The pods are eaten by cattle, and sometimes by people, for their sweet pulp and seeds. The screw-pod mesquite or tornillo is *Prosopis pubescens,* another southwestern plant, whose pods are coiled in a tight spiral, resembling a screw.

MESS, in the army and navy, and particularly the latter, a company of officers, or crew of a ship, who eat, drink and associate together; in military language, a sort of military

ordinary, established and regulated by the rules of the service, for all the officers in a regiment, and supported by their joint subscriptions, supplemented by a small government allowance. Similar institutions are extended to the non-commissioned officers of a regiment. The enlisted men mess by companies as a rule, but often it is desirable to cut the company into squads for mess purposes. The post commander usually appoints some officer to take charge of mess arrangements. In active service the officers are apt to mess with their own troops, but in camps they have their separate mess. In the navy it is usually convenient to have a captain's mess, another for the wardroom officers, another for the junior officers, another for the warrant officers, etc. The men's mess for the sailors or marines is styled the "general mess," but this is usually divided into sections, as a matter of convenience. It has become common to employ ammunition passers as mess attendants.

MESSAGER, André Charles, French composer: b. Montluçon, 30 Dec. 1853. He received his musical education at École Niedermeyer, Paris, and subsequently studied under Saint-Saëns in the same city. He was appointed organist at Saint Sulpice in 1874. A symphony of his won the gold medal of the Société des Compositeurs in 1876. In 1880 Messager became music director at Sainte Marie-des-Batignolles. Three years later he completed the comic opera by Bernicat, 'François des bas bleus,' and in 1885 produced his own operettas, 'La Fauvette du temple' and 'La Béarnaise.' The following year saw the production of his ballet, 'Les deux pigeons' at the Opéra. Messager's reputation, however, was most enhanced by the comic opera 'La Basoche,' produced at the Opéra Comique in 1890 and in English in London in 1891. It was followed by the operas 'Madame Chrysanthème' (1893); 'Mirette' (1894); 'Les petites Michus' (1897) and 'Véronique' (1898); 'Les dragons de l'impératrice' (1905); 'Fortunio' (1907); 'Béatrice' (1914). Messager became conductor at the Opéra Comique in 1898; was one of the directors of the Covent Garden Opera in 1901–07, and first conductor at the Paris Grand Opéra after 1907. From 1907 to 1914 he was also joint director with Broussan of the Grand Opéra and after 1908 was conductor of the Concerts du Conservatoire. Died, 24 Feb. 1929.

MESSALA (mĕ-sā'lą) **CORVINUS, Marcus Valerius,** Roman soldier, orator and writer: b. about 65 B.C.; d. about 2 B.C. He received a part of his education in Athens, returned to Rome before the second triumvirate and joined the Senatorial party. He fought with Brutus and Cassius at Philippi, 42 B.C., and afterward attached himself successively to Antony and Octavius, served at the battle of Actium, 31 B.C., and the same year was chosen consul. He subdued Aquitania, of which he was made proconsul and was honored with a triumph. For a time he was a prefect of Rome and held the office of augur. Messala was the friend of Horace and other distinguished men of the age, a zealous patron of literature and art, notably of the poet Tibullus, and one of the most eminent of Roman orators.

MESSALINA, Valeria, Roman empress. She married Claudius (later emperor) in 38 A.D.; bore him a daughter, Octavia, and a son, Britannicus; proved herself vicious, licentious and vulgar by her many open amours; and in her husband's absence formally married Gaius Silius, whom she attempted to make emperor. Claudius refused or delayed to punish her, and Narcissus, the emperor's favorite, had her put to death (whether with Claudius' knowledge or not is not known) in 48 A.D. Her reputation was whitewashed in Stahr's 'Agrippina, die Mutter Neros' (1880).

MESSENE, mĕ-sē'nē, the capital of Messenia in Peloponnesus, founded by Epaminondas (369 B.C.) after his victory of Leuctra over the Lacedæmonians, and situated at the foot of the hill of Ithome, the fortress of which formed the acropolis of the new capital. The latter was surrounded by massive stone walls, flanked with towers, of which there are still considerable remains at the modern village of Mavromati. The Greek Archæological Society, in 1895, excavated a colonnade and other parts of the ancient agora. Messene with its acropolis was, next to Corinth, the strongest city of Peloponnesus. It was supplied with water from a fountain called Clepsydra, the spring of which still exists.

MESSENIA, mĕ'sē'nĭ-a, Greece, a department in the western part of Morea (Peloponnesus), bounded on the south and west by the Ionian Sea. The population of this administrative division, including the refugees from Asia Minor, is 248,000. The greater part of the surface is a fertile plain, but there are mountainous lands in the east and northeast. Kalamata, the capital, is in the southeast on the Gulf of Koron (Messenian Gulf). When Messenia was a state of ancient Greece its chief cities were Methone and Pylos (Navarino). Later Messene (Mavromati) was the capital, and the strong mountain fortress was Ithome. A ridge of Mount Taygetus separated Messenia from Sparta. Messenia is celebrated for the long struggle of the inhabitants with the Lacedæmonians in defense of their liberty. In the first Messenian War (743–723 B.C.) the Lacedæmonians, with the Athenians, invaded Messenia. For 20 years the Messenians defended themselves valiantly under their king Aristodemus, who in consequence of an answer of the Delphic oracle which promised them the victory on condition of the sacrifice of a virgin of the royal family, offered his own daughter as the victim. Her lover, to save her life, declared her to be pregnant by himself; and Aristodemus, to prove her innocence, stabbed her with his own hand, and caused her to be opened and sacrificed. The Messenians, though for some time successful, were finally obliged to submit by the loss of Ithome. About 40 years after they again rose, and thus commenced the second Messenian War (685 B.C.), which ended in their entire subjugation. A part of the Messenians emigrated to Sicily, and there founded Messana (see Messina) on the site of the ancient Zancle (668 B.C.). Those who remained were reduced to the state of helots. After 200 years of servitude they again took up arms. This third Messenian War lasted 10 years (465–455 B.C.), and resulted in the expulsion of the Messenians from the Peloponnesus. Epaminondas restored them, gathering together the exiles from the various lands

in which they were scattered. Within the space of 85 days they completed and fortified Messene (369 B.C.) and maintained their independence till the country was conquered by the Romans (146 B.C.). The Messenians remained true to their customs, manners and language through all changes of fortune.

MESSHED. See MESHED.

MESSIAH, The, is a term which is, in John i, 41, and, in John iv, 25, but without the article, applied to Jesus of Nazareth, as the appointed king of the Kingdom of God. The Greek word which is the translation of the Aramaic term meaning Messiah, namely, *χριστός*, in English Christ, is used of Jesu in this same sense throughout the New Testament. The word Messiah itself is a modified transcription of the Greek word *Μεσσίας*. The extract transcription would be Messias, as the word appears in the Authorized Version in both the passages cited above, and the form Messiah is due to the influence of the form of the original Aramaic and Hebrew word. For the word which appears in Greek as *Μεσσία* was, in Aramaic and Hebrew, מָשִׁיחַ (Māšîᵊḥ). All the forms of the term Messiah, as well as the Greek equivalent, *χριστός*, and the English Christ, mean Anointed One, and refer to Jesus, when applied to him, as God's Anointed King.

In the Old Testament, מָשִׁיחַ (Māšîᵊḥ) (English Messiah) is used, in a few cases, without the article, and as an adjective, of priests, who were anointed to their office (Lev. iv, 5 and 16, vi, 22). But, in the definite sense of the Anointed One, or the Messiah of Jehovah (the Lord's Anointed), it is used, with a very few possible exceptions, only of kings. Thus, in 1 Sam. ii, 35, it is used of the kings of Israel in general. In 1 Sam. xii, 3 and 5, xxiv, 6 and 10, it is used of Saul; and, in 2 Sam. xiv, 21, xxiii, 1, it is applied to David. In Lam. iv, 20, it denotes Zedekiah, King of Judah; and, in Isa, xlv, 1, it is applied to Cyrus, King of Persia. Two possible exceptions to its use to denote kings may be found in Psa. cv, 15 (quoted in 1 Chron. xvi, 22) and Hab. iii, 13, where it seems to be used to mean the nation of Israel as the priest people of Jehovah, although, even in these cases, it may refer only to the king. In Daniel ix, 25 and 26, it is very difficult to decide the true meaning of this word, because of the great uncertainty in relation to the correct interpretation of these verses. According to the various interpretations which have been given to them this word would mean a high priest, a royal ruler, or that great king of the kingdom of God known to us as Jesus of Nazareth. It is not certain, however, that both times it is used in these verses it has the same meaning. In Psalm ii, 2, the best and most probable interpretation would make the term denote the great coming king known to us as Jesus the Christ. This is the only passage in the Old Testament in which this term can be taken with any reasonable degree of probability to refer to our Saviour.

In the post-canonical literature, the first clear application of the term Messiah to the great coming king of Israel is found in the Psalter of Solomon, dating from about 63 B.C. In this poetical collection we have a full and clear description of this king and his work under this title. There are, indeed, in the Sibylline Oracles and the Book of Enoch, expressions and terms which must be supposed to refer to the coming and expected king of Israel, but the name Messiah is not used in these writings.

While the pre-Christian use of the term Messiah to denote the divinely appointed and eternal king of the Kingdom of God is thus limited, the Old Testament abounds in statements and teachings relating to this king, and that form of the Kingdom of God in which he is to be ruler and sovereign. In some of the passages relating to this final form of the Kingdom of God it is said that Jehovah himself will be the king, as he was, in reality, in all the history of the kindom of Israel. Consult as examples of passages of this kind, Isa. ii, 2–4, Isa. xxxiii, 22, Ezek. xx, 33, Ezek. xxxiv, 15, Zeph. iii, 15, Zech. xiv, 16. In other passages, in harmony with the idea that, while Jehovah was always the real king of Israel, he was represented in the government by a vicegerent king, his anointed on the throne of David at Jerusalem, it is declared that a great and eternal coming king, who, in some of the passages, is stated to be of the line of David, shall reign as king in the final form of the Kingdom of God. Among the passages of this kind may be cited Psa. cx, Isa. ix, 6 and 7, Jer. xxiii, 5–8, Jer. xxx, 8 and 9, Ezek. xxxiv, 23 and 24, Ezek. xxxvii, 24 Hosea iii, 4, Micah v, 2–5, Zech. ix, 9. Just what will be the relation, in person and in nature, between Jehovah and this Davidic king, is not made clear, or even asserted, in the Old Testament.

Independently, therefore, of the use of the term Messiah, there was a natural and sufficient basis in the Old Testament for the widely-spread belief in regard to the coming of a future Davidic king called the Messiah, which appears to have existed in the time of Jesus. In this belief Jesus himself shared, and this king Messiah, or Christ, he both virtually and formally claimed that he himself was. A virtual claim of this kind is found in Matt. xvi, 13–20, and in the parallel passages, Mark viii, 27–30, and Luke ix, 18–21, and also in the act done by Jesus, of which we have the record in Matt. xxi, 1–11, and the parallel passages, Mark xi, 1–10, and Luke xix, 29–40. A formal claim of Jesus to be the Messiah is found in John iv, 25 and 26.

The rejection of the claims of Jesus by the Jewish nation, and the continuation in that nation of the belief in a coming Messiah, were the occasion of the appearance in Jewish history of several who claimed to be the Messiah after the time of Jesus. Of all these the one who was most generally received as the Messiah by the nation, and who accomplished the most for his people, was Simon bar Cochba (or bar Kozeba), who flourished 130–35 A.D., in the reign of the Emperor Hadrian. For two years and a half, bar Cochba reigned as king, and, at the head of an army of 200,000 men, defied the might of Rome. But, in the end, he and his nation were both crushed beneath the power of Rome.

The Jews of the present day are not all of the same opinion in regard to the Messianic hope. The conservative, or Orthodox, Jews are still looking for the coming of the Messiah, the

great king of the line of David. With the liberal, or Reformed, Jews, so far as the term Messiah is used at all, it is made to stand for a personification of a system of ideas and doctrines, and the coming of the Messiah will be the universal acceptance and the world-wide domination of Jewish ideas and the Jewish religion.

MESSIAH, The ('Der Messias'). Klopstock's 'Messiah' is German Pietism's most important contribution to literature and modern Germany's most pretentious epic poem, consisting of 19,458 dactylic hexameters as compared with the 12,310 of Homer's 'Odyssey.' When the first three cantos appeared in 1748 in the 'Bremer Beiträge ('Bremen Contributions') it took the public a year to get accustomed to the novelty of its form and content, after which its success was unprecedented, its readers awaiting with impatience the next two cantos, which appeared in 1750, and the next five, which appeared in 1755. On these 10 the fame of the work must rest; for the following cantos, appearing five in 1768 and five in 1773, were probably as disappointing then as tiresome now.

The theme is the redemption of mankind, and the poem starts with Christ's entry into Jerusalem on Palm Sunday, the most exalted subject at hand for the young Jena student of theology, who at the academy of Pforta had come under the influence of Milton through the writings of Bodmer. On going to Leipzig in 1747 Klopstock recast the prose beginnings into hexameters, thus breaking with the traditional Alexandrines and loosing a storm of criticism on his head from the school of Gottsched, while that of Bodmer applauded. It has been said that the work of no German poet before Richard Wagner aroused such controversy. Goethe's Autobiography tells us that his father banished the book from the house because of its blank verse. However, Klopstock broke the sway of the French in epic verse as Lessing did later in the drama, demonstrating the nearer affinity of German to English. He learned a great deal from Milton, but his nature was essentially lyrical, contemplative, mystic, and he often smothers the epic possibilities of his subject in a flood of fervent, more or less seraphic, religious ecstasy, which exhausts the reader. Instead of strong contrasts, going from darkness to light, from misery to bliss, he attempts to portray a mental state of continuous, dazzling brilliancy. Instead of an alternation of clashes there is a contemplative passivity, from which result endless repetitions and long drawn out speeches; so to speak, a massive elaboration of the text of Händel's oratorio, which was but seven years older. Certain descriptions, however, are very successful, such as those of hell, the council of the devils, their punishment through transformation, the trips through the universe made by angels and devils, and especially the vision of the last judgment. Klopstock's taking over of the Miltonic cosmography gave him the opportunity of portraying a great struggle between the powers of light and darkness for the soul of Christ and therefore of man, but instead his angels paralyze their adversaries with a look, which method of warfare is not epic, though perhaps pietistic.

His forte is to excite feeling and to lend expression to the inexpressible even when his characters become speechless. No German poet before him had so mastered the capacities of the language, whether in choice of words or in rhythmic cadence. In a sense he became the creator of modern poetic diction. A flood of epic imitations on various biblical subjects attested his contemporary influence, and all the younger poets of his day learned from him, but the 19th century admired him from an ever increasing distance. Edition: 'Werke,' Franz Muncker (Vols. I and II, Stuttgart 1893); 'Messias und Oden' (Halle 1910). Lessing 'Briefe,' XV, 'Brief: Ueber das Heldengedicht: Der Messias' (1753).

CARL E. EGGERT,
Assistant Professor German, University of Michigan.

MESSINA, mĕs-sē'nä, Sicily, town and seaport, capital of the province and on the strait of the same name. Messina is walled, flanked by bastions and defended by a citadel on the south and several forts both on the east and west. The harbor is one of the best in the Mediterranean and so much resembles a sickle that the town took its original Greek name from that implement, called *zancle.* Fronting the harbor is a broad quay called the Marina, adorned with statues and fountains and forming a favorite promenade. The streets of the old town are narrow and dirty, but the modern town, built

since the earthquake of 1783, is generally composed of houses of two stories and has spacious streets, well paved with blocks of lava. Among the public edifices are included nearly 50 churches, many of them of great beauty and adorned with fine sculptures and paintings. The cathedral is a Gothic structure, with a somewhat heavy exterior, but supported within by vast pillars of granite, supposed to have belonged to a temple of Neptune. The viceroy's palace, the archiepiscopal palace, the senate house, grand seminary, college, large and well-endowed hospital, numerous convents, two theatres, lazaretto and arsenals are some of the other buildings worthy of notice. The manufactures consist chiefly of silk goods. The trade, both transit and general, is extensive. The principal exports are silks, olive oil, linseed and other seeds, wheat, wine and spirits; salted fish, licorice, lemon-juice, sumac, essences, rags, sulphur, etc. The tunny and other fisheries are carried on to a considerable extent. A destructive earthquake visited the locality Dec. 28, 1908 destroying about half of the buildings and causing the loss of more than 77,000 lives. Messina has a government university, founded in 1549, which had 10,664 students in 1948, in departments of law, medicine, science and classics. It has also a naval seminary and a number of elementary schools. Messina, under the name of Zancle, is said to have been founded 1004 B.C.; the Messenians obtained possession 668 B.C.; it became a free city of Rome 241 B.C.; the Saracens captured it in 831; Richard I of England with his Crusaders spent six months there in 1191, sacking the town on leaving; from 1282 to 1713 the Spaniards ruled, though the French held it briefly 1676–1678; in 1743 a plague killed 40,000 of the inhabitants; in 1783 an earthquake caused large loss of life; in 1854, 15,000 died of the cholera; in 1860 the city came under Italian rule, and was peaceful and prosperous until the 1908 tragedy. In World War II the Germans made their last stand in Sicily at Messina. Soon after it was abandoned, it was occupied by Allied forces. Pop. (1943) 192,051.

MESSINA, Strait of (ancient SICULUM FRETUM), a channel which separates Sicily from Italy and connects the Tyrrhenian and the Ionian Sea. It has a length of about 20 miles, and gradually widening toward the south, attains a width of 12 miles; but in the north, where it is narrowest, does not exceed two miles. The depth is great, in some parts over 4,000 feet, and a strong current continually running with the tide makes the navigation somewhat difficult, but by no means so formidable as was fabled by the ancients, to whom the rock of Scylla, and the whirlpool of Charybdis, on the opposite side, but at some distance to the south, seemed so dangerous that it was generally believed to be almost impossible to avoid the two.

MESSMATES, Animal. See COMMENSALISM.

MESTA, Perle, American public official: b. Sturgis, Mich., c. 1890. Her father William B. Skirvin made a fortune in real estate and oil in the Southwest in the 1890's. His daughter, educated in private schools at Galveston, Texas, accompanied him in 1906 to Oklahoma City where he organized the American Oil and Refining Company, some of the profits of which he invested in constructing the 14-story Skirvin Hotel. Perle Skirvin, ambitious to become a singer, studied voice and piano until her marriage in 1916 to George Mesta, president of a Pittsburgh machine-tool manufacturing company. During World War I Mr. Mesta was a dollar-a-year man in Washington, while his wife directed the Washington Stage Door Canteen. After the war Mrs. Mesta became a member of the board of directors of her husband's company and they traveled extensively in Europe, generally on business trips. Until Mr. Mesta's death in 1925 they were frequent guests of President Calvin Coolidge at the White House. A few years later, on her father's death, Mrs. Mesta fell heir to a second large fortune. In 1929 she acquired a mansion at Newport and became known as a society hostess. Two years later she was presented at the Court of St. James's. Active in the American Women's Party since 1935, she was chairman of its public relations committee and council member in 1949. Believing the Republican Party had rejected Wendell Willkie's liberal principles, Mrs. Mesta changed her political faith in 1941. She moved from New York to Washington and in a few years gained the reputation of the foremost unofficial hostess in the national capital. Before his nomination for the vice presidency she became acquainted with Senator Truman and his family and was the first to entertain him after his election. Remarkably successful as a fund raiser for the 1948 campaign, she was co-chairman of President Truman's inaugural ball in January 1949. The following June she was nominated minister to the Grand Duchy of Luxembourg, the Senate confirming on July 5. The third American woman to attain so high a rank in the diplomatic service, her resignation was accepted, effective April 13, 1953.

MESTIZOS, mĕs-tē′zōs, or **METIS** (Spanish, mixed), half-breeds; those of mixed blood, especially those descended from Indian and Spanish or Indian and Portuguese.

MESURADO, mĕs-ŭ-rä′dō, **Cape,** Republic of Liberia, West Africa, on the west coast, near the seaport of Monrovia.

MESZAROS, mä′sä-rôsh, **Lázár,** Hungarian revolutionary soldier and patriot: b. Baja, County of Bács, Feb. 20, 1796; d. Eywood, Herefordshire, England, Nov. 16, 1858. He was first educated for the church, but subsequently studied law at Pest. In 1813 he was summoned to join the Hungarian Army by the Emperor Francis I; later entered the Austrian Army, taking part in the campaigns of 1814–1815 against Napoleon, and subsequently in Italy; and several years later was appointed colonel. He was in Italy in 1848, serving as a colonel in a Hussar regiment, when he was chosen by Count Batthyány, who had formed a new Cabinet, for the portfolio of minister of war. Acting in this capacity he was largely instrumental in bringing the Hungarian Army to a high degree of efficiency. In September of that year, having gone to the scene of war in the south, he was defeated before the Rascian ramparts of Szent Tamas. When Austria purposed the subjugation of Hungary, Mészáros took command of

the Hungarian forces in the north, but on 4 January his army was routed at Kaschu. In April 1849 after the declaration of independence he again took command of the Hungarian forces, but after the defeats at Szöreg and Temesvár in August he fled to Turkey. He subsequently lived in England, France, the island of Jersey, and in 1853 came to the United States.

META, mā'tä, a river of South America, which has its rise on the eastern slope of the Andes Mountains near Bogotá in Colombia. It is formed by the junction of two small mountain streams, which unite about 40 miles southeast of Bogotá; then flows east-northeast into the Orinoco; a course of about 650 miles.

METABETCHOUAN, mĕt''ą-bĕt-choo-ăn', Canada, a river of Quebec flowing into Lake Saint John from the south. It is a broad stream, 90 miles long, and navigable for a considerable distance. The celebrated Falls of Metabetchouan over 230 feet high are near its mouth.

METABOLISM (Greek *μεταβολή* a change), the whole series of physico-chemical processes connected with the manufacture of protoplasm and with nutrition and growth. Under the term is included all those changes by which various energy transformations are made possible in the human body. It has been divided into constructive metabolism (anabolism), and destructive metabolism (katabolism). The former comprises the processes by which the substances taken as food are converted into protoplasm, while katabolism is the means by which the protoplasm is broken down into simpler products, such as the excretory or waste matters. Metabolism thus comprises the elementary vital phenomena of plant and animal life. These are the occurrences associated with changes of substance, of form and of energy. All organisms undergo continual changes of their substance or protoplasm, etc., alterations of their form and transformations of the energy which they get from the environment. The human body is essentially an energy transformer. Thus as regards food, since all living matter is continually undergoing decomposition, it must take in substances that contain all the chemical elements of which it is constructed, but the food differs with every form of cell. Plants live chiefly on inorganic substances and animals on organic, that is, material already prepared; no animal being able to live on simple inorganic compounds. Among animals there is a remarkable adaptation to a single kind of food. For example the larva of the fur-moth lives exclusively upon the hairs of fur, which consist of pure keratin; this substance, which is closely allied to proteid, is therefore capable of furnishing all the elements necessary for the formation of the protoplasm of this caterpillar. Dogs when worked hard have been found to be able to live on pure proteid food. On the other hand, according to Verworn, it is impossible for an animal to live solely on carbohydrates or fats, or even on the two together, since there is no nitrogen in these substances.

Vital motion or metabolism is a complex sharply characterizing living organisms, and the taking in of food and the excretion of waste products give to the organism the material with which to regenerate itself and to grow. Metabolism is increased by heat, the consumption of oxygen being increased in cold-blooded animals, but warm-blooded animals undergo a decrease under heat. Thus man in winter has a much more active metabolism than in summer, since he consumes more food at low temperatures.

It is claimed by Verworn that every species of animal possesses a specific metabolism, and that under certain conditions products of metabolism may stimulate an animal to increased growth, while under other circumstances they may retard growth. Thus the usually deadly uric acid in moderate amounts exerts a favorable influence on the size of larvæ of sea-urchins. Illustrations are afforded by experiments in raising snails and water-fleas (*Daphnia*) in small volumes of water; besides the diminished volume, the water fouled by their excretions may not only dwarf but gradually kill them, or produce changes of form. Metabolism is more active in the young than in the adult. Between 9 and 14 a boy requires as much food as a full-grown man, and during the next five years more than a man. The same is not true of girls who increase the amount of metabolism up to the 11th year.

Consult Verworn, 'General Physiology' (New York 1899); Bayliss, 'Principles of General Physiology' (New York 1915); Du Bois, E. F., 'Basal Metabolism in Health and Disease' (3d ed. 1936); Macleod, J. J. R., 'Carbohydrate Metabolism and Insulin' (1926).

METACENTRE, *in hydrostatics,* the point of intersection of a vertical line passing through the centre of gravity of a floating body as a ship *in equilibrio,* and a vertical line through the centre of gravity of the fluid displaced, if the body be turned through a small angle, so that the axis takes a position inclined to the vertical. If the metacentre is above the centre of gravity, the position of the body is stable; if below it, it is unstable. In shipbuilding a vessel must be so designed that its metacentre (its changing centre of buoyancy) is not likely to oscillate so as to permit capsizing.

METACHROSIS, the change of color brought about in the surface of certain animals, either voluntarily or involuntarily, to make them conform to their surroundings. It is exhibited in many of the lower animals as a protective device, especially in cuttlefishes, caterpillars, various amphibians, especially frogs and certain lizards, notably the chameleons. The dark pigment to which the brown or gray colors of metachroic caterpillars are due is deposited in the cells of the outer skin, while the green coloring matter is found in the underlying fat; and, as Carpenter says, experiments have shown that the presence or absence of both kinds of pigment is determined by the surrounding objects through the quality of the light reflected from them, the suppression of the superficial dark pigment allowing the deeper green to show through the skin, and thus give its hue to the caterpillar. It has been shown that the formation of the dark pigment is hindered by the action of certain yellow rays which are absorbed by dark objects, but reflected from green leaves and shoots. The process of change in squids, frogs, etc., through nervous and muscular control of pigment sacs, called chromatophores, is somewhat different, and is explained in the article CHAMELEON.

The power possessed by these animals of adapting their color to their surroundings is of value in insuring protection from enemies. Consult F. E. Beddard, *Animal Coloration* (New York 1892).

METACINNABARITE, a native sulphide of mercury, occurring amorphously, when it is dark gray or black, or in tetrahedral crystals. To its black color it owes its early popular name, ethiops mineral.

METAGENES, Cretan architect of the 6th century B.C. He and his father, Chersiphron, both of Knossus, collaborating possibly with Teodoro di Samo, were the architects of the Artemision (Temple of Artemis) at Ephesus.

METAGENESIS, or **HETEROGONY,** a form of parthenogenesis. It is that type of alternation of generations (q.v.) in which one generation produces only asexually, by division or budding, the other generation exclusively by laying eggs. It occurs during the life history of a number of scattered species of Metazoa, including the coelenterate, *Obelia; Salpa,* the tunicate (a chordate animal); and two or three marine worms. In the *Obelia* there is a plant-like asexual form which gives rise to sexual, free-swimming medusae. The medusae produce eggs and sperms which unite in water and develop into asexual colonies. Another case is that of the aphids, whose asexual individuals produce multitudes of young by budding, the next generation consisting of males and females, the latter laying fertilized eggs. An individual of the first generation is called the nurse; of the second, the sexual animal. The special significance of metagenesis has not been determined, although the process possibly insures better and wider distribution of individuals than could be effected by only the budding colony. In many sexually producing plants there is a similar alternation of asexual and sexual generations.

Another term for this phase of reproduction is heterogony (or heterogenesis), which Hertwig defines as "regressive alternation of generations." He mentions another form of heterogony where two generations with different forms and structure alternate. For example, a hermaphroditic threadworm (*Ascans nigrovenosa*) lives in the lungs of frogs; it produces a form (*Rhabdonema nigrovenosum*) which lives in mud, and which lays eggs giving rise to the ascaris of the frog.

METAHEWETTITE, a dark red mineral consisting of hydrous calcium vanadinite occurring in microscopic crystals with uraninite and carnotite at several localities in Utah. Probable composition $CaO.3V_2O_6.9H_2O$; a source of vanadium.

METAL WORK, any work done in metals, but especially handiwork practiced as a decorative art, in which the materials are metal and the designs are executed in repoussé or relief. This may be accomplished either by carving or expert hammering as of thin sheet metal. The term includes jewelry (q.v.) and goldsmith's work; hence its materials are often precious metals and its end personal adornment. But it is often applied to larger work and especially to metal decoration in architecture, apparently a later development in the arts than was the jeweler's trade, which flourished in classical antiquity, and everywhere seems to have quickly followed the most primary knowledge of metallurgy in industrial evolution. The Middle Ages were the great period of metal work, notably in connection with Gothic art. Even the more valuable metals were lavishly used in this epoch, as before in the Byzantine period, and since in the architecture of the Greek Church, above all in Russia. One of the foremost instances of Italian metal work is to be found in the altars of St. James at Pistoria and of the baptistery of St. John in Florence. Each of these was the work of a line of great artists, whose elaborate work upon them covered more than a century. Cellini (q.v.) was the greatest metal worker of the 16th century. Even more important than this work in silver and gold are the great bronze doors in the Florence baptistery, one by Ghiberti and another by Pisano, each the product of a score of years of labor, and both dating from the 15th century. Wrought iron work began to be used in the 12th century; between the 13th and the 18th centuries in the shape of gates, grilles and screens in ecclesiastical art, and in German locks and hinges of great beauty, it came to its most perfect form. The sepulchral brasses of German, French and English churches should also be mentioned. See BRASSES.

METAL-WORKING, a term describing any method by which the shape, size, physical form, or contour of metal is changed. This change can be the result of hammering, filing, rolling, machining, casting, grinding, stamping, forging, extruding, cold-heading, or any of several other hand or mechanical methods. It embraces every forming process from the handicrafts to the most complicated mechanical forming. Metal-working includes the manufacture of jewelry (using precious metals) and the production of components of such items as automobiles, radios, toasters, business machinery, railroad equipment, home appliances, industrial equipment, and any item or commodity made of metal or having metal in its make-up.

Lathes.—Lathes machine or turn work of cylindrical section by rotating it against a tool. The lathe holds the work between two rigid supports called centers or in such devices as the faceplate or chuck, attached to the end of the spindle. Operations performed on a lathe include turning, facing, drilling, boring, threading, spinning, and skiving. Since the lathe is probably the most versatile machine in a machine shop, there are a variety of types, all of which operate on the same basic principles.

The principal parts of a lathe are the headstock, holding the driving mechanism and rotated spindle; the tailstock, supporting the back center and capable of being clamped at any point along the bed or frame; and the carriage or turret, carrying the tools. On some lathes, where the work is chucked on the headstock, a tool turret is substituted for the tailstock.

The capacity of a lathe is designated by the maximum diameter of work which can be rotated and the maximum distance between centers. Lathes with collet-type or hollow chucks are rated by the maximum bar diameter which will go through the largest collet capable of being taken by the hollow spindle.

The speed lathe is the lathe in its simplest

form, with a simple headstock, tailstock, and tool post for wood turning, metal spinning, and polishing. Work of large diameter can be mounted on the left end of the headstock, outside the bed. Tools are hand actuated.

The engine lathe, most common of all, chucks work or holds it between centers. The cutting tool is power actuated.

The toolroom lathe is a conventional machine with accessories necessary for accurate toolroom work. It usually is equipped with a wide range of spindle speeds and has a relatively short bed

The duplicating lathe is for duplicating the shape of flat or round templates on the workpiece. Air, hydraulic, or electric mechanisms control the tool movement to reproduce the template shape. Irregular contours, steps, tapers, shoul ders, recesses, radii-formed surfaces, and bore contours can be made.

The gap lathe is a variation of the engine lathe in which the ways are stopped short of the headstock, far enough to provide a gap in the bed for swinging large-diameter work.

Spinning lathes are those in which a chuck or a pattern of the part is attached to the spindle and a blank or disk of metal is held against the form by the tailstock support. With the workpiece revolving, a spinning tool is applied to the work from the center outward, forcing the metal against the form.

Turret lathes are special production lathes They are basically the engine lathe with a multifaced toolholder (turret) mounted across the bed and another turret, usually square, mounted on the tool cross slide. Turrets can be rotated to present different tools to the work. The turret lathe can be horizontal or vertical.

Semiautomatic lathes are machines into whicl the operator loads the work and starts the cutting cycle. The machine completes a series of predetermined cutting operations automatically, then stops itself. As many as 10 or 20 tools may operate on the part from front and rear toolslides.

The screw machine, either hand or automatic, is a machine which handles round, hexagonal, or square bar stock. A variation, the chucking machine, is equipped to handle castings or forgings In the class of the automatic screw machine there are two types, the single spindle and the multiple spindle. These machines are designed for production work. The principle of design is the use of a chucking or work-holding means with a slide for carrying the end-working tool turret and a carriage or cross slide on the bed for mounting either a second turret or some other form of cross slide toolholder. These toolholding devices are adapted for mounting a variety of tools, which are applied singly or in groups to the work.

The single spindle machine provides for feeding one piece of bar stock through the spindle for machining. The multiple spindle type has a series of spindles, each carrying a bar of stock. These bars are presented in turn by an indexing mechanism to the successive tools, each tool taking a cut. The operation is automatic. Finished parts, as they are cut off the bar stock, drop into collecting trays. In the chucking machine, parts are machined in a similar manner, but usually are loaded into and removed from the machine by hand.

Milling.—The milling machine ranks with the lathe in usefulness. It consists fundamentally of a power-driven, rotating spindle, which drives the cutter; and a movable table, which holds the work. There are three basic milling machines: knee and column, manufacturing, special. Many variations and combinations of these basic machines consist of features of one type combined with features of others for special work. The milling machine produces accurately one or more machined surfaces on a piece of work by one or more rotary milling cutters having single or multiple teeth or cutter blades. It machines flat or irregularly shaped surfaces, cuts gear teeth and threads, and performs drilling, boring, and slotting operations.

The knee and column type is the standard, general purpose machine made in three styles: plain, universal, vertical. Manufacturing millers are standard machines for quantity production of identical parts. These are made in several styles, including plain milling machines with horizontal spindles, duplex machines with opposing horizontal spindles, the automatic knee and column, the automatic fixed bed, the automatic rise and fall, the tracer controlled, and the hydraulic controlled equipment. Special types are those in which units of standard machines are assembled in different arrangements for certain classes of work. Typical of such special equipment is the planer miller, incorporating the reciprocating action of the planer table with the cutting action of one or more milling heads.

The classification of a machine having as many variations and combinations as the milling machine is extremely difficult. However, on the basis of appearance, design, and use, there are several comparative classifications: knee and column and fixed bed, plain and universal, bench and floor mounting, horizontal and vertical spindle, hand or power feed, jobbing and manufacturing, reciprocating and rotary table, thread milling and planetary milling, and diesinking. Milling machines frequently are incorporated into transfer lines, automatically performing multiple milling, facing, boring, and other machining operations.

Drilling.—This operation is accomplished on a variety of types of equipment and has several allied operations. Boring, reaming, counterboring, and spot-facing are operations dealing with the formation and finishing of holes. A drilling machine is basically a machine designed to hold a tool and to provide means for furnishing it the proper rotating speed and axial feed. Stationary, portable, bench, floor mounted, round column, box column, horizontal, vertical, fixed position spindle, radially adjustable spindle, fixed head, sliding head, table feed, spindle feed, single spindle, multiple gang spindle, multiple cluster spindle, single way, multiple way, and spindle reversing for threading are included in the types of drilling equipment. Drilling can be performed also on boring machines, lathes, milling machines, and jig borers. The distinction between boring and drilling, generally, is that a fluted tool, rotating on its own axis, is used in drilling, whereas in boring a single pointed tool is used which rotates on the axis of a spindle carrying the tool.

On the basis of types of drilling equipment there are many major classes of drilling machines. The sensitive drill is hand fed. The standard drill is similar to it, except that it is built to handle heavier work and has a power feed. The gang drill has a number of spindle machines mounted on a common base with a common worktable, where speed and feed of each spindle

is independent. The adjustable multiple spindle drill consists of a number of spindles operated simultaneously from a single drive through a gear box and universal joints. The radial drill is equipped with a vertical spindle tool carried on a horizontal arm, which may be swiveled about a vertical column, and the spindle can be adjusted radially on the arm. The horizontal drill is a special purpose machine with horizontal spindle movement. The way drill is an arrangement of spindles on machine ways with adjustable spindle position.

Since drilling is probably the most common of machining operations, extremely diversified methods have been developed for this operation. In cases where precision accuracy of hole size, concentricity, taper, and location are required, jig boring machines frequently are employed.

Closely allied to drilling, other machining functions are done on the same type of equipment. Reaming is the finishing and final sizing of holes drilled. Counterboring often is performed to act as a recess for bolt heads. Machined parts frequently are spot-faced for work location in subsequent machining operations or for providing a more suitable area to drill. Drilling machines with reversible spindles often are used in tapping or threading holes to receive bolts because the reversing feature permits the tap or threading tool to be retracted from the hole without destruction of the threads.

Boring.—Boring machines normally are used to form holes of larger diameter than can be drilled and for extreme accuracy. Drill diameters are somewhat limited, but single-point tools can be mounted on spindle extensions or boring bars of any diameter. Also single-point tools can be mounted on stationary toolholders and the work can be revolved against the tool. There are several types of boring machines, including the horizontal boring, drilling, and milling machine; the table, floor, planer, and vertical kinds; and a variety of special types.

One type of vertical boring machine is the vertical turret lathe, which is simply a large lathe stood on end with the headstock on the floor and rotating the work in a horizontal plane. A turret carries the tools. The standard or best-known vertical boring mill handles work of large size. The rating of its machine capacity depends upon the diameter of the largest piece which can be accommodated on the table. The jig borer is basically a vertical spindle milling machine, but is the ultimate in machine tools from the standpoint of accuracy. It will locate accurately and make holes in dies, jigs, fixtures, and gages. Three systems of precision measurement are used in jig boring: end-measure location, precision lead-screw location, and scale and microscopic location.

One specially designed boring machine of high accuracy, using the end-measure system of tool locating, is a patented combination boring and milling machine known as the Jig-Mil. Special boring machines include those employed for such work as boring automotive and Diesel cylinders, locomotive connecting rods, and locomotive steam cylinders.

Grinding.—This is a metal-working technique which removes material with an abrasive wheel instead of a cutting tool. It does not wear down the metal, but actually cuts it away in very small chips. Closely allied to grinding are polishing, honing, lapping, and buffing. In polishing and buffing the abrasive wheel is replaced with cloth, rawhide, or composition wheels, and the abrasive is applied to the wheel or work in liquid, paste, or stick form.

There are many types of grinding machines, ranging from a grinding wheel placed on a hand drill, or on a foot-operated whetstone to a highly complicated machine for special form-grinding. Power for grinding may be electricity, air, or mechanical shaft drive, and operation may range from complete hand control to complete automatic control.

Snaggers and swing frame grinders are used to dress or to clean up castings or billets of metal in a reducing mill. Plain and universal center-type cylindrical grinders, through-feed or in-feed centerless, and both horizontal and vertical spindle surface grinders are common production equipment in machine shops.

Grinding machines provide both a means of rotating a solid or segmented grinding wheel and a method of positioning work against the rotating wheel. Cylindrical grinders are used to grind work of a generally cylindrical cross section, as it is held in position between centers. Centerless grinders grind work of a cylindrical cross section, but the work is held in position by a combination of the grinding wheel, a back-up or driving wheel, and a bar mounted just below and between the two wheels. Work placed on the bar is held between the wheels and the driving wheel rotates it against the rotating grinding wheel. Surface grinders are used to grind flat surfaces either with the periphery of the wheel (horizontal spindle machine) or the face of the wheel (vertical spindle machine).

Included in a numerous assortment of types of grinding machines are: internal grinders for grinding holes, and centerless, cylindrical, portable, disk, and belt grinders. Belt grinding employs an endless belt, usually cloth, to which abrasive particles have been glued. The belt is driven over sheaves and the work to be ground is held against the moving belt.

The type of work performed on grinders is practically limitless. Snaggers, offhand grinders, swing frame, portable, flexible shaft, and disk grinders are used for rough work. Very thin abrasive wheels are employed for cutting to length such items as bar stock and tubes. Belt grinders, polishers, buffers, vertical and horizontal grinding machines are used for surface grinding. Precision work is done on tool-post, cylindrical, centerless, internal, surface, and belt grinders. Special grinders are built for such precision work as finishing crankshafts, camshafts, gears and worms, ball-bearing balls, cams, and threads. Special grinders are in frequent use also for grinding single-point cutting tools, drills, milling cutters, reamers, taps, dies, and knives. Crush grinding, wherein a special form or shape is maintained in the grinding wheel by a device which trues the wheel form automatically, often is employed for grinding special contours.

Face grinders resemble the planer in operation and may employ cup, circular, or segmented grinding wheels. The table, on which the work is mounted, or the wheel may be movable. The way grinder is a special machine for grinding the ways or beds of machines. Profile or contour grinding is similar to pantograph milling, in that models or templates guide the grinding wheel.

Cast-iron or bronze laps or shoes, to which is added oil containing an abrasive, frequently are

used in lapping. Abrasive sticks are usually employed in honing, and are reciprocated in a bore to finish it.

Broaching.—A machining method which increased in popularity during World War II is broaching. This is a technique in which one or more cutters having a series of teeth are drawn across the surface to bring that surface to a desired shape and finish. The teeth of the broaching tool are arranged one behind the other. They increase in height from the first or roughing teeth to the last or finishing teeth, so that each tooth removes the same amount of metal. The last or finishing teeth bring work to finished size. The tool, which may be pulled or pushed through the work, may be mounted horizontally or vertically. The press is used as the motive power for the tool.

Advantages of broaching are several. It permits high production, extreme accuracy, good work finish, and requires little in the way of operative skill. Except in hole broaching, where the broaching tool locates itself, fixtures are necessary to position the work against the cutting tool.

Normally the tool is pulled through the work in horizontal broaching, but in vertical broaching the tool may be pushed or pulled through the work. Several separate broaching tools may be mounted in the machine so that a number of parts may be finished in one complete cycle of the tools. Continuous broaching machines are special machines which provide means of carrying the work past the tool.

The broaching tool ranges from a tool of the size and shape of a hack-saw blade to one, six, or eight inches wide for finishing in one pass the head of an automobile engine. Tools completely surrounded by teeth are frequently used in finishing holes and in cutting internal gears or internal splines.

Gear Cutting.—Gear cutters are special metal-working machines and are of three types: nongenerating, generating, and profiling or tracing. Machines which form teeth by cutting spaces in the gear blank are nongenerating machines. These spaces are the shape of the cutter. These nongenerating machines use three types of tools: the single-point cutter on a planer or shaper; the circular-form cutter for rough and finish cutting of spur and helical gears, and rough-bevel gears; and the broach-form cutter for internal and external gears.

Machines of the generator type form the gear tooth by a relative rolling motion of the cutter and work. The rack-shaped cutter is employed for spur, helical, and herringbone gears; the pinion-shaped cutter is for internal and external spur, helical, and herringbone gears; the hobbing cutter is used for spur, helical, herringbone, and worm gears; one or more single-point tools serving as a rack can cut bevel, internal-spur, and helical gears; the circular side-cutting tools are for cutting spiral-bevel or hypoid gears.

Gears are cut also in machines using templates or master forms. Bevel and coarse-pitched spur gears often are cut in this manner, using single or double tools.

Planers, Shapers, Slotters.—These are classed in one group, because they perform the same general type of work, that of machining flat surfaces with a single-point tool. The tool is stationary in planing and the work is moved past it by a reciprocating table. The work is held stationary in shaping and slotting and the tool is pulled or pushed over it. Planers are generally employed on large pieces. In handling small pieces the choice depends upon the number of pieces desired. If only a few pieces are necessary, the shaper is likely used. If many are required, they may be mounted in tandem on a planer bed and planed. The fundamental difference between the shaper and the slotter is that the shaper tool travels horizontally and the slotter tool travels vertically or, by a machine adjustment, slightly off the vertical.

Ordinarily on all three machines the tool is pushed through the work. However, a draw-cut arrangement is possible. Planers ordinarily machine flat surfaces on work too large for milling or shaping, the tool being supported on a cross-rail extending over the reciprocating table from one or between two columns. Single-column planers are called open-side planers.

By mounting a spindle rotating mechanism and a milling cutter on the crossrail or the column, a combination-type machine can be built. Such a machine may plane, mill, drill, or bore without changes in setting of the tools or work.

A gear shaper, using a circular cutting tool shaped like a gear, is a special vertical shaper for cutting gear teeth. For large gears the gear shaper may be operated horizontally.

Pressworking.—Under the classification of pressworking of sheet metal are such processes as punching, stamping, drawing, and blanking. Presses may be actuated manually, by gravity, mechanically, hydraulically, or by steam. The operation of a press is basically the reciprocating movement of a ram and a stationary table. A forming punch is attached to the ram, and a hollow die, into which the punch nests with proper clearance, is positioned in the table. Sheet metal, placed over the die, is forced by the punch into the die, assuming its shape, or is sheared as in trimming or blanking.

Presses may have multiple rams which have a combination of actions: single, double, triple. This feature provides for a combination of actions on the workmetal. For example, when a deep cup-shaped part or a part of deep contour, such as an automobile fender, is to be formed, one ram descends and firmly grips the sheet around the edges. The second ram descends subsequently and forms the part. The first ram is known as the hold-down and keeps the metal from being drawn unevenly into the die. This type of press is known as a double-action press.

In mechanical presses application of power can be by gears, screws, cranks, cams, toggles, and knuckle joints. Pneumatic, steam, and hydraulic presses are actuated by air, steam, and oil or water (as the names imply). The position of the ram with respect to its direction of travel can be vertical, horizontal, or inclined. Presses are also identifiable by the design of the frame or housing of the equipment. Such designs include bench, floor, inclinable, open back, straight side, arch, gap, adjustable bed, horning, wiring, shearing, trimming, and gang types.

Presses are used for many other purposes in addition to the forming of sheet metal. Actually, as the word press implies, the machine performs a pressing or squeezing action. Consequently any working of metal by pressure is usually done in a press. Such operations include: straightening of sheet or metal sections, hot or cold forging, extruding, trimming, swaging, up-

setting, blanking, shaving, punching, piercing, bending, drawing, embossing, coining, shearing, sizing. Metal may be broached by placing a broaching tool in proper position in a press and, by special arrangements of the ram and bed, metal parts may be staked or assembled by bending edges or flanges in such a manner as to hold rigidly the metal assembly.

Rolling Mills and Draw Benches.—Into a special category of metal-working machines falls equipment usually found in metal-producing plants. These machines comprise principally rolling mills and drawing equipment. Rolling mills consist of an arrangement of two rolls, between which metal is passed for reduction in cross-sectional area, change in cross-sectional shape, or reduction in thickness. In the mill, provision is made to apply pressure through the rolls to the metal being rolled. Metal may be rolled either hot or cold.

Billet, blooming, plate, bar, pipe, sheet, strip, and structural mills are rolling mills. When rolling mills are arranged one behind the other (in tandem), connected by conveyor equipment, and properly controlled, the arrangement is called a continuous mill, because the work proceeds from one stand of rolls to another automatically, each stand successively working on the material. In rolling material of uniform cross section the rolls are cylindrical in shape. In rolling products such as channels, railroad rails, angles, channels, and I-beams, the rolls are shaped to produce the desired forms. Frequently the rolls coming into contact with the work are backed up by heavier rolls which aid in applying the desired pressures. Such mills are known as four-high mills, because four rolls are arranged vertically one above the other.

Hot-rolled bars, tubes, and rods often are cold-drawn to reduce diameter, to increase the strength of the product and to improve its finish. Hard Tool steel, tungsten carbides, and diamonds are materials used as dies. Holes of precise diameter are pierced in the dies, and the work is pulled through these holes. By making these holes slightly smaller in diameter than the starting material, the work diameter is reduced. The action of the die on the workmetal, called cold working, increases its strength and tends to make the surface bright and smooth. Tool steel and carbides are employed as die materials for drawing bars, tubes, and wire; occasionally diamonds are used in drawing fine wire. In wire drawing, a series of draw dies often is arranged in such a manner that the wire passes through the successive dies, each die further reducing the thickness or gage of the wire.

Other Metal-working Machinery.—There are several other classes of metal-working equipment for sawing, thread cutting, die casting, extruding, cold heading, and casting. Sawing is common and well known in woodworking, and the technique applied in metal-working is similar. Familiar types of saws include the hack saw, the band saw, the circular saw, and the abrasive disk.

Threading machines are of two basic types: those which cut threads and those which form threads by rolling the metal between two dies. Tapping machines, pipe threaders, lathes, milling machines, and special machines are employed in cutting threads. The thread rolling machine places an external thread on a part by rolling the part between two dies, either flat or circular, in which threads already have been cut, and the pressure forces the metal in the part into the grooves of the die.

Casting is a process by which liquid metal is either poured or forced into a sand, plaster, or metal mold, which is hollow, and to which the metal conforms in shape. In die casting, metal is forced into a die chamber under pressure, thus forming a part to rather exacting dimensions.

Extrusion is an operation by which metal, either hot or cold, is forced through a die, to which shape it conforms. A ram forces a metal slug, placed in a hollow chamber, forward through the die. The fundamental difference between drawing and extruding is that in the former the metal moves backward over the punch of the press, whereas in the latter the metal is forced forward ahead of the punch or ram.

Cold heading is used in the manufacture of such common items as bolt heads, nuts, bearing balls. In this process the cold metal is forced by pressure into hollow dies and assumes the shape of the die.

No description of metal-working machinery could include all the types and combinations of types. The job to be done determines what machine shall be used, and if the job is big enough special machines often will be built to do it. Also, necessity will occasionally develop new uses for old machines, especially where experimental work is being done with equipment on hand.

METALLIC CURRENCY. See CURRENCY.

METALLOGRAPHY, study of the structure and construction of metals by the combined aid of the microscope and photography. It grew naturally out of the microscopic study of the structure, first of wood, next of rock, then of meteorites, and appears to have been first applied to metals by Henry Clifton Sorby, of Sheffield, in 1864, immediately following his study of the microscopic character of meteorites.

The process of micrometallography consists simply in photographing a picture of a small portion of a prepared section of a metal, magnified by the microscope to anything from 20 to 1,000 times.

The section of metal is first polished by means of emery, etc., according to the character of the section, and generally the polishing is followed by etching of the surface of the section, by a solution of nitric or other acid; or the section may be treated electrolytically by being exposed for a brief period in a bath of dilute sulphuric acid through which a current is passed. By etching the section it is thoroughly cleaned, and the actual structure of the metal is thus much more clearly revealed.

Photographic pictures obtained have thrown an entirely new light on the microstructure of metals. Taken systematically at each stage in the smelting, working, or heat treatment of a

metal, they enable us to watch, in effect, what goes on in the metallic mass when passing from the molten to the solid state; when cooling in the solid; when under mechanical treatment as in rolling, drawing, or hammering; when stressed beyond its elastic limits; and in the process of tempering. The results of micrometallography as applied to the study of the formation of alloys, particularly those of steel and aluminum, have proved of exceptional importance.

Indeed, our real knowledge of the formation of alloys only began with the introduction of this process, which has demonstrated that all metals when solid are crystalline, and that the structure of a metal must, therefore, be in accordance with the laws which govern the formation, growth, and arrangement of crystals. See also IRON; METALLURGY.

METALLOID, mĕt"l-oid, *in chemistry,* any nonmetallic element. These are 13, namely, sulphur, phosphorous, fluorine, chlorine, iodine, bromine, silicon, boron, carbon, nitrogen, hydrogen, oxygen, and selenium. The distinction between the metalloids and the metals is slight. The former, excepting selenium and phosphorus, do not have a metallic luster; they are poor conductors of heat and electricity, are generally not reflectors of light and not electropositive; that is, no metalloid fails of all these tests. The term seems to have been introduced into modern usage instead of nonmetals for the very reason that there is no hard and fast line between metals and nonmetals, so that metal-like or resembling metals is a better description of the class than the purely negative nonmetals. Originally it was applied to the nonmetals which are solid at ordinary temperatures.

METALLOPHOBIA, a morbid fear of metals or metallic objects.

METALLOSCOPY, *in medicine,* study of the influence that the contact of certain metals is capable of exercising on the human body, especially on the nervous system. The study was initiated by the French physician Dr. V. J. A. Burq (1822–1884) in 1849 upon observing that application of plates of certain metals (gold, platinum, copper, iron) on anaesthetized parts of the bodies of hysterics restored cutaneous sensibility. This led to his originating the therapeutic method called metallotherapy (q.v.).

METALLOTHERAPY, *in medicine,* the treatment of diseases, especially neuroses, by applying metallic discs to the skin and by the ingestion of metallic solutions. It was originated by a French physician, V. J. A. Burq.

METALLURGY, formerly defined as "the art of extracting metals from their ores"; now broadened to include "and the fitting of them to industrial uses." It therefore comprises the various types of smelting and metal extraction; the production and refining of metals and alloys; casting, rolling, and forging; heat treatment and such matters as welding, brazing, and soldering. Many of these branches of metallurgy are themselves large industries.

When a company covers all the activities from mining the ore and smelting to fabricating and finishing final products, it is known as an "integrated" company . A good example is Anaconda Copper Mining Company which with its chief subsidiary, American Brass Company, embraces all phases of the industry from mining to finishing and selling the semifinished and final products made from copper and its alloys. Steel foundries and iron foundries are examples of "nonintegrated" companies, because they start with such raw materials as pig iron and scrap, and usually do not mine ore and smelt their own pig iron.

The two broad divisions are often described as *process metallurgy* and *physical metallurgy,* the first covering smelting and the operation of foundries, rolling mills, and producing plants; the second covering the treatment, handling, and fabrication of metals after they have been produced. A process metallurgist must be familiar with chemistry, particularly at high temperatures, because he is usually dealing with molten metal and slags and their reaction on each other. He must also be a fuel technologist and understand the principles of furnace design.

A physical metallurgist is mainly concerned with the internal constitution of the metals and alloys he is dealing with, and such subjects as heat treatment, plastic flow of metals, and the effect of stresses on metals. His work is based principally on physics as well as chemistry, and he must be familar with modern research tools, such as the microscope, the use of X-rays, and the spectroscope. This branch of the industry attracts many women as well as men. Indeed, both major divisions (which interlock in many cases) make use of all the teachings of science, and almost every metallurgical company either has its own research laboratories, or employs people with scientific training to keep informed on new developments and adapt them to its own operations.

Physical metallurgists are also employed by many industries that are not thought of as strictly metallurgical, such as automobile and tractor companies, or the electrical companies like General Electric or Westinghouse. This is because such companies use various metals and alloys in large quantities and have to test them and investigate their properties so as to employ them to the best advantage; also to carry out research work to discover new alloys with properties needed for new products. One of the most interesting developments in recent years has been the production of metals to resist high temperatures and still remain strong, which metals are making possible the development of gas turbines and jet propulsion. Much of this work has been done by the research departments of the large electrical companies with assistance from the makers of tool steels and of metals and alloys already used for high temperature and corrosion-resistant applications.

The history of metallurgy is very long and of great interest. It is true that metallurgy goes back far beyond recorded history. Man became

a tool-and-metal-using being very early in his development, and his continued progress depended very largely on his ability to produce and fabricate metals. The first major use of metals was for offensive and defensive weapons, such as swords, spears, and shields, and this still continues. Everyone realizes how dependent modern armies are on the metals and alloys that go into tanks and guns, projectiles and bombs, modern airplanes, as well as such equipment as radar, proximity fuzes, and signalling devices.

Our civilization, as we know it, depends on modern farming; on transportation by land, sea, and air; on rapid methods of communication; on books and newspapers; on good roads and highways; on machine tools and tools in general, whether they are saws and hammers or bulldozers and tractors; on homes and buildings equipped with modern plumbing, radiators, elevators, and washing machines, along with numerous other pieces of equipment. All of these, together with almost every feature of our civilization, depend on metals in one form or another, such as copper and steel wire, cast iron radiators, tungsten filaments in incandescent bulbs, or steel reinforcing rods in concrete roads and buildings, or steel plate in bridges, ships, and freight cars. The list of metals and alloys and their uses is almost unlimited.

The metallurgist has reason to feel proud of his contributions to these various fields. Many examples could be given. For instance, newspapers, books and printed or typewritten material of every kind depends very largely on type-metal, a direct contribution of applied metallurgy, and of the work of men in many countries. One of the great inventors of the world was Sir Henry Bessemer (q.v.), who as a boy spent many hours in his father's type-metal foundry and there learned the art of founding and the mixing and alloying of metals. This experience stood him in good stead later in life when he was trying to develop improved metal for cannon, which lead to the discovery of the Bessemer process of steelmaking. The great development of this country after the Civil War was largely due to improved transportation helped by the manufacture of rails and other railroad material by the Bessemer process, which was able to turn out the enormous tonnage of steel that was needed at relatively low cost.

Our enormous petroleum industry depends very largely on the cheap transportation afforded by pipelines carrying crude oil and refinery products such as gasoline and kerosine. During the war one became impressed with the importance of this method of transportation when the Big Inch (24-inch diameter), and the Little Big Inch (20-inch diameter), lines were constructed to carry crude oil from Texas to the Atlantic Coast, a distance of about 1,400 miles. Pipeline transportation carries about one ninth of the freight tonnage moved in the country. It has been made possible by the development of seamless and welded pipe, and also by the development of welding lengths of pipe together by means of the oxyacetylene torch and the use of proper welding rods.

The gradual discovery of new metals, or of metals and alloys with new properties, was responsible for most of the development of mankind. Economists measure the importance of countries and races of people by their use of metals; and in the daily and weekly discussions of business, among the most important factors are the production and use of metals or the condition of the industries that produce them or depend on them.

The first important use of metals is often referred to as the Bronze Age when stone implements and weapons were replaced by those of metal. Bronze, an alloy of copper and tin, was not the only metal of this period; gold and some of its alloys were used for jewelry and ornaments; native copper was used in addition to bronze; and steel was undoubtedly used, but rusted away, while bronze resisted the elements. The Bronze Age was succeeded by the Iron Age, then the "steel age," and it is often stated that we are now living in the "alloy steel age," because of the great development of special or alloy steels in recent years. Everyone remembers the great growth of the automobile industry since about 1900 or 1905, but very few know how this was due in large part to the development and application of alloy steels. The Model "T" Ford when first introduced was not a success because the springs would not stand up and many broke. This serious problem was solved by the use of chrome-vanadium steel for springs, properly heat treated. Mr. Kent-Smith, an English metallurgist, came to Detroit and helped work out this problem, because of the experience he had gained in England with this new steel. Then as the automotive industry grew, there also developed the wide application of many alloy steels, and of heat treatment, one development helping the other to their great mutual advantage.

Machine-shop practice has been revolutionized by the use of alloy tool steels and of special materials known as sintered carbides. It is said, even now, that modern machine tools do not develop all the advantages that high-speed tool steels and sintered carbides offer when compared with the old carbon tool steels of 40 to 50 years ago.

Properties of Metals.—Metals have characteristic properties distinguishing them from other materials. We usually think of them as relatively heavy, and with the exception of magnesium and aluminum, their density is fairly high, ranging from a specific gravity of 1.74 for magnesium to 22.4 for iridium and 22.5 for osmium. Of the well-known metals, tin is 7.3; iron, 7.87; copper, 8.94; lead, 11.34; and gold, 19.3. Mercury, or quicksilver, which is the only metal liquid at ordinary temperatures, is 13.55. Uranium is a heavy metal with a density of 18.7.

Most metals have a characteristic luster, generally regarded as their most striking quality, and usually accompanied by a particular color. For instance, everyone associates copper or silver, gold or platinum, with their respective colors, and the colors of many metals and alloys determine their use in industry or art.

All metals are crystalline, that is, their atoms are arranged in a regular order, and this property is of great importance in the study and application of metals and alloys. The atom arrangement is spoken of as the crystal lattice, and by means of examination with X-rays the size of the crystal cube or hexagon or rhomb can be determined, as well as the distribution of the atoms within the cube or other shape. Many metals exist in allotropic forms and the crystal lattice is different in these various forms. Sometimes the external crystal forms are very beautiful and easily visible, as in the case of antimony when slowly cooled from fusion, or such alloys as ferrochrome; but even if the crystal form is not apparent to the eye, it is made evident when specimens are properly prepared and examined with the microscope or by means of X-rays. One result of this crystal formation is that metals and alloys often have directional properties, that is, the physical values vary in different directions, and advantage is taken of this property many times in using them.

The internal structure of metals is closely

allied with the physical properties and is greatly influenced by the treatment the metal has undergone. If cooled slowly from the molten condition, the structure is usually coarse and the material is brittle with little toughness. If, however, the metal is cooled quickly as in the case of die castings poured into a metal mold, then the structure is usually fine and the material has considerable toughness. The coarse cast structure of steel ingots and many other cast materials is broken up by forging and rolling, with corresponding improvements in physical properties, but the greatest and most striking change in the structure of metals is brought about by heat treatment; the variations in physical properties brought about by the latter method are amazing. This is one of the great fields of work of the physical metallurgist.

The hardness of metals varies greatly. Some, like lead, can be indented with the thumbnail. Others, like properly made tungsten carbide, approach the diamond in hardness and are of great value as dies for the drawing of wire, or as tools for machine-shop use in cutting other metals and materials. Here again, proper heat treatment causes great changes in hardness. Properly annealed tool steel can be readily machined and shaped, but after hardening and tempering it is one of the hardest of materials. Many metals vary greatly in hardness according to the work imposed on them. Annealed brass is comparatively soft, but if cold-worked between rolls, or drawn through dies, the hardness is greatly increased. Brass sheet is sold and used in various hardnesses or tempers.

One very important property of metals is plasticity. Some, like gold and lead, can be readily shaped because they are plastic, and even steel has a plastic range. Because of this property, sheet metal can be shaped by deforming between dies, as in the case of automobile bodies and fenders, or brass cartridge cases. Also many sheet metals are "spun" into various symmetrical shapes such as reflectors. This property is influenced by temperature, and most metals are heated to make them more plastic before they are rolled or forged.

Many other properties of metals might be mentioned, such as corrosion resistance. The great growth in the use of stainless steel is familiar to everyone and is largely due to its resistance to the corrosion of the atmosphere and of many liquids (such as milk), of foods and of chemical solutions. The petroleum refining industry makes use of many metals and alloys because of their corrosion resistance, and this is true of various other industries, such as the production of synthetic fibers like rayon and nylon.

Fuels.—Both the process and the physical metallurgist depend on high temperatures in many of their operations for the attainment of which fuels are needed. Every type of fuel is used in some operation or other, and improvements in the use of fuels, or availability of new fuels, register advances in both practice and economy. A good metallurgist must be thoroughly familiar with the fuels available and adapted to the particular operation he has in mind.

The usual classification of fuels is solid, liquid, and gaseous. Typical examples of solids are coal and coke; of liquids are fuel oil and tar; and natural gas, city gas, producer gas, coke oven gas or blast furnace gas are typical gaseous fuels. However, many others are used for particular purposes, such as hydrogen or acetylene for welding, cutting, and brazing operations, and wood or charcoal in certain cases. Electricity is used as a source of heat to an increasing extent. There are many kinds of electric furnaces, depending on the heat of the electric arc. The aluminum industry is based on its own type of arc furnace. The steel industry makes use of arc furnaces in the production of stainless steel, most types of tool steel, and a very large tonnage of alloy steels. A great many heat treating furnaces are of the resistance type, the electric current passing through resistors made of many different materials. Such furnaces can be automatically controlled with great precision. Since about 1935 high frequency heating has come into rapidly increasing use, where again electricity is the source of heat.

The subject of fuels is of increasing importance because the cost of metallurgical operations depends very largely on the kind and amount of fuel used. All fuels possess certain advantages over others. Metallurgical coke is strong and porous. It supports the weight of the charge in a blast furnace or a foundry cupola, and when subject to the blast of cold or hot air near the bottom of the furnace burns very readily, giving the heat necessary for the operation. Nothing has been found so far to replace it economically.

Gaseous fuel can be stored and transported very easily. It also burns readily and leaves no ash. Both gas and the air for combustion can be closely controlled, and burners can be automatically regulated, which means that furnace temperatures can be controlled. The furnace atmosphere can be made oxidizing or reducing as needed, or even neutral in character. Long furnaces can be designed which have burners at the proper intervals.

Most important of all, when using gaseous fuels, the principle of regeneration of heat can be applied. The hot waste furnace gases can pass through chambers filled with a checkerwork of fire brick, and the bricks heated, before the gases pass to the chimney stack. Then by means of suitable valves, the gaseous fuel and air for combustion can pass through such chambers before entering the furnace, and to the heat of combustion is added the physical heat from the bricks. This was the principle discovered by Friedrich Siemens in England in 1856 which made possible the construction of improved glass-melting furnaces and the open hearth furnace for steel making, and this principle is used in coke ovens and many types of heating furnaces.

The subject of fuels and their proper and economical use is so important that most metallurgical plants, especially steel plants, have a fuel engineer with a well staffed department.

Refractories.—Mention should be made of refractory materials which can resist heat and the corrosive action of molten slags and hot gases. They vary from natural sandstones and fireclays to artificial refractories of many kinds. Every advance or improvement in refractories leads to improvement in furnace design and construction, with consequent development of better metals and alloys, or to reduction in costs.

The usual classification is acid, basic and neutral. Typical examples of acid materials are fireclay and firebrick, silica brick and silica sand. The only basic refractories used in industry are calcined magnesite and either raw or calcined dolomite, although Henri Moissan, the French

scientist, did much of his research work with the use of blocks of burnt lime. Chromite, graphite, carbon blocks, and water-cooled metal shapes are among the neutral refractories. Another refractory greatly used in foundry work is molding sand, which stands the temperature of molten metals and forms the molds into which such metal is poured. All of these refractories are important. They form the hearths, walls, and roofs of furnaces; mixtures of fireclay and graphite are used for crucibles; ladles are lined with firebrick or with fireclay, and without refractories metallurgical operations could not be carried on. Research in the field of refractory materials is extensive, and many metallurgical plants carry on their staff a refractories engineer.

The reason for the designation "acid" and "basic" is that such materials have an acid or basic chemical reaction at the working temperature of the operations. For instance, an electric steelmaking furnace usually has a basic hearth of calcined magnesite. This allows and requires that the molten slag covering the bath of molten steel must be basic in character, which in practice means it is rich in lime and can absorb and hold impurities removed from the liquid steel during the refining operation.

The discovery of successful basic refractories to be used in steelmaking practice was made by a young Englishman, Sidney Gilchrist Thomas, about 1875, and was one of the great inventions of the world, making possible basic open hearth and basic electric steel production, and also the basic Bessemer or Thomas process so widely used in Europe.

Fluxes.—Among the raw materials used in process metallurgy are fluxes. Limestone is the most widely used, particularly for blast furnace operations, and burnt lime is used a great deal in other operations. The functions of a flux are to unite with waste materials in the charge at the working temperatures and form a fusible, readily flowing slag which can be easily tapped from the furnace and removed. Calcium fluoride or fluorspar is another flux used in foundry operations, open hearth and electric steelmaking, and also in the production of aluminum.

Furnaces and Equipment.—The types of furnaces and equipment used in metallurgical operations vary tremendously. There are many kinds of blast furnaces. In the production of tin, lead, copper matte, and pig iron, for instance, the size and design vary according to the materials being treated, the fuels used, and the daily tonnage desired. An iron blast furnace is circular in cross section. At the bottom is the hearth or crucible in which the molten materials accumulate, metal on the bottom covered by the lighter slag. The time of tapping varies; slag may be removed every two hours, and the iron every four hours. The lines or design of the furnace vary with the kind of ore being treated. The daily tonnage output also varies from 5 tons to 1,600 tons, according to the size of the furnace and how it is blown or operated. The products of an iron blast furnace must all be either liquid or gaseous, otherwise the furnace would choke up and have to shut down.

A copper blast furnace, on the other hand, is usually rectangular in cross section. A lead blast furnace is generally circular; the molten lead does not collect in the furnace but flows continuously.

The products of these furnaces may be used as such, but in general have to be refined. For instance, lead is treated in large kettles, as they are called. Pig iron is made into steel in various ways: by melting with steel scrap and refining in open hearth furnaces, or by blowing air through it in Bessemer converters. Tool steel is usually made by melting carefully selected scrap steel with some pig iron in electric furnaces and refining under the proper slags. In all these stages of the refining operations, many varied and particular types of furnaces are employed.

For the further working up of the materials, the metals are melted in crucibles, reverberatory furnaces, cupolas, open hearth furnaces, or electric furnaces; then they are cast into the required shape, with the use of many special types of equipment particular to foundries, varying in accordance with the kind of castings being produced, such as magnesium alloys, aluminum alloys, brass or bronze, cast iron, or the many varieties of steel. Or again, the metals may be cast into ingots and fabricated into a great variety of rolled or forged shapes, with the required variety of heating furnaces and forging equipment, such as hammers or presses, drop hammers or forging machines. In regard to rolling mills, there are a great many different kinds turning out sheet, strip, bars, rails, plate, or structural shapes. Other types of mills produce pipe or seamless tubes, while different kinds of equipment are required for cold rolled sheet, extruded bars and shapes, or cold rolled bars. Then again there are the special drawing machines for producing wire, some of them small in size, while others are assembled in groups and cover a great deal of ground.

All such equipment requires the trained experience of mechanical and electrical engineers for design and operation, and the metallurgist must be able to understand their work and cooperate with them.

In addition to these types of equipment, an entirely different approach is seen in the field of wet metallurgy, which is closely akin in its methods to the work of the chemical engineer. In such cases the ores or raw materials are usually finely ground and concentrated by various methods such as flotation. Then the concentrates are often roasted or calcined to put them into suitable condition, after which they are leached with various solutions, such as dilute acids or solutions of various salts. The solutions containing the metals are then filtered and subject to precipitation, or the metal salts may be crystallized from solution, after which the precipitates or crystals may be again dissolved and the solutions subject to electrolysis in special cells.

Summary.—This brief presentation of metallurgy attempts to show what a broad field of work is covered by the metallurgist. It gives an explanation of why men specialize in their own small part of this field, and why large companies devote all their activities to the metallurgy of a particular metal, or even to one actively connected with one metal, such as the production of brass or bronze castings, or the manufacture of wire rope. It also shows that there is ample scope for the inventive genius of mankind and for efforts in the line of administration, business, and production. See also articles ALUMINUM; BLAST FURNACE; COPPER; COPPER AND BRASS INDUSTRY; ELECTRIC FURNACES; ELECTROCHEMICAL INDUSTRIES; ELECTROMETALLURGY; IRON; STEEL; also on the separate metals.

GEORGE B. WATERHOUSE.

METALS. Chemists and physicists usually divide the elements into three classes: metals, nonmetals, and inert gases. Metals constitute by far the largest group. At present the periodic table is based on 96 elements; and of these, 73 are considered as metals, including arsenic and silicon (sometimes classed as metalloids), and also including the new elements neptunium and plutonium; 13 as nonmetals including boron and carbon (also sometimes classed as metalloids); 6 as inert gases; and there are still two ill-defined spaces (atomic numbers 85 and 87). The metals are subdivided into light metals, heavy metals, and rare earth elements.

Metals were formerly considered to be those elements which had a metallic luster and were good conductors of heat and electricity; this is still the standard adopted by the average person, to whom metals are not merely elements such as iron, copper, or gold, but also the great class of alloys including such materials as steel, brass, bronze, pewter, or cast iron. The chemists define metals as those elements giving hydroxides which form bases such as sodium or potassium, while the nonmetals give hydroxides which form acids, such as sulphur. It is difficult to make a sharp, clear distinction, since some of the elements meet both requirements.

The following classification is a modern acceptation of the metal grouping in the periodic chart:

Class 1a. Light Metals: lithium, sodium, potassium, rubidium, cesium, and the recently undiscovered atomic number 87, francium.

Class 2a. Light Metals: beryllium (or glucinum), magnesium, calcium, strontium, barium, and radium.

Class 1b. Heavy Metals: copper, silver, and gold. These are typical metals and were known to the ancients. They exhibit the traditional qualities of metals. They are hard, heavy, opaque, malleable and ductile, take a good polish, and are good conductors of heat and electricity. The other three traditional metals are iron, tin, and lead. The properties of these six gave rise to the general classification of metals.

Class 2b. Heavy Metals: zinc, cadmium, and mercury.

Class 3. Heavy Metals and Rare Earth Elements: (3a) aluminum, gallium, indium, and thallium; (3b) scandium, yttrium, lanthanum, and actinium; rare earth elements, cerium, praseodymium, neodymium, illinium (atomic number 61), samarium, europium, gadolinium, terbium, dysprosium, holmium, erbium, thulium, ytterbium, and lutecium.

Class 4. Heavy Metals: (4a) silicon, germanium, tin, and lead; (4b) titanium, zirconium, hafnium, and thorium.

Class 5. Heavy Metals: (5a) arsenic, antimony, and bismuth; (5b) vanadium, columbium (or niobium), tantalum, and protactinium.

Class 6. Heavy Metals: (6a) polonium (atomic number 84); (6b) chromium, molybdenum, tungsten, and uranium. All of these 6b metals have been used as alloying agents in steel, the first three being extremely important in this respect. Uranium was the heaviest known metal until the production of neptunium and plutonium which are made from uranium.

Class 7b. Heavy Metals: manganese, masurium, rhenium, and neptunium.

Class 8. Heavy Metals: iron, ruthenium, osmium, and plutonium; cobalt, rhodium, and indium; nickel, palladium, and platinum. It will be noticed this class contains the so-called platinum group of metals.

Properties.—Bismuth has the peculiar property of being heavier when liquid than when solid. Like water, it reaches its greatest density just before becoming solid. The relative densities of some common metals in the solid and liquid state are shown in the following table, compiled by the English metallurgist, Sir William Roberts-Austen, working with metals of the purity available to him years ago.

Metal	Specific gravity of solid	Specific gravity of liquid
Iron (pig)	6.95	6.880
Zinc	7.20	6.480
Tin	7.50	7.025
Copper	8.50	8.217
Bismuth	9.82	10.550
Silver	10.57	9.510
Lead	11.40	10.370

As mentioned in the article on metallurgy (q.v.), all metals are crystalline. This is often shown when metals or alloys are fractured. Fracture may be brought about by repeated shock or vibration. Such a fracture is now spoken of as a "fatigue fracture" and is often shown by broken automobile axles or railroad rails. The shock and vibration have not induced the crystalline structure, which was there already, but have brought about the failure.

When heated, metals show a red, then yellow, and finally a clear dazzling white color. The temperatures corresponding to these colors are approximately:

Colors	Degrees C.	Degrees F.
Visible color, black red	525	970
Dull red, low red	700	1290
Red, incipient blood red	800	1470
Cherry, bright red	900	1650
Bright cherry	1000	1830
Dull orange	1100	2010
Bright orange	1200	2190
White	1300	2370
Bright white	1400	2550
Dazzling white	1500	2730

A similar visual color scale is used extensively in the drawing or tempering of carbon tool steels. These temperatures are approximately:

Color	Degrees C.	Degrees F.
Faint straw	205	400
Straw	227	440
Deep straw	246	475
Bronze	270	520
Peacock blue	282	540
Full blue	310	590
Light blue	338	640

Two important properties of metals are malleability and ductility. Both are dependent on the strength and toughness of the metal. Malleability permits metal to be hammered or rolled into thin sheets or foil; ductility permits it to be drawn into wire. The relative malleability and ductility of the common metals, as given by Charles H. Fulton, are shown below:

Order	Malleability	Ductility
1	Gold	Gold
2	Silver	Silver
3	Copper	Platinum
4	Platinum	Iron
5	Palladium	Nickel
6	Iron	Copper
7	Aluminum	Palladium
8	Tin	Aluminum
9	Zinc	Zinc
10	Lead	Tin
11	Nickel	Lead

The malleability of gold is well known. When beaten into gold leaf, it is translucent, the transmitted light being a bluish green. Malleability depends on plasticity, which is affected by temperature. If a metal can be rolled or hammered at ordinary temperatures but not at higher temperatures, it is called "red short." This is the case with many alloys such as certain brasses. If the reverse conditions obtain, the metal is called "cold short." This is the case with many

alloys and is one reason why most materials are heated before rolling or forging. In other words, plasticity generally increases with temperature. The malleability and ductility of many metals and alloys are amazing. Everyone is familiar with silver foil, tin foil, or aluminum foil; and in regard to ductility, a great many materials can be drawn into wire too fine to be seen by the unaided eye.

Physical Constants.—Some physical constants of the metals are shown in the following table. The chemical symbol follows the name of the metal. The atomic number is the position in the periodic chart:

Metal (and symbol)	Atomic number	Atomic weight	Specific gravity	Melting point °C.
Actinium (Ac)	89	228.00	*	*
Aluminum (Al)	13	26.97	2.70	657
Antimony (Sb)	51	121.76	6.62	630
Arsenic (As)	33	74.91	5.73	814 [a]
Barium (Ba)	56	137.36	3.50	850
Beryllium (Be)	4	9.02	1.85	1284
Bismuth (Bi)	83	209.00	9.80	271
Cadmium (Cd)	48	112.41	8.65	320.9
Calcium (Ca)	20	40.08	1.55	851
Cerium (Ce)	58	140.13	6.90	775
Cesium (Cs)	55	132.91	1.90	26
Chromium (Cr)	24	52.01	7.14	1550
Cobalt (Co)	27	58.94	8.90	1490
Columbium (Cb)	41	92.91	8.57	1950
Copper (Cu)	29	63.57	8.94	1083

* Not yet determined. [a] Sublimes.

A great many of the metals shown in the preceding table are produced in large quantities in very pure condition, approaching chemical purity. This is particularly true of those which are precipitated by electrolysis from their chemical compounds. This includes a long list of familiar metals, among which are: aluminum, copper, gold, lead, manganese, iron, nickel, platinum, silver, tin, and zinc. All of these find uses as pure metal in addition to the application of much larger amounts of more impure or commercial material.

Alloys.—Mention has been made of alloys, and these should be considered in greater detail. The great consumption of metals in commerce and the arts is as alloys, which are composed of two or more metals or even nonmetals. For instance, carbon (sometimes considered as a metalloid) is present in practically all steels, and the amount and condition in which it exists determine the properties of all the ordinary steels and many of the special or alloy steels. Sulphur, another nonmetal, is found in all steels, and a very large tonnage of steel is made in which it is introduced specially to influence the properties, and the percentage present is carefully controlled.

Most of the metals with which we come in contact are alloys. For instance, pure gold is too soft for jewelry and coins and is generally alloyed with copper. Our standard for coins is 900 fine, that is, 900 parts per 1,000. Gold has remarkable covering power in regard to color. Pure gold is 24 carat; 18 carat gold is generally used for jewelry, that is, 18 parts per 24, or 75 per cent. Even as low as 9 carat, the gold color still persists. Another alloying metal often used with gold is silver. White gold is very familiar. It is usually a complex alloy containing nickel and zinc to give the white color, with copper and often a small percentage of manganese. Another type of white gold is an alloy of gold and palladium. Some gold alloys for use in jewelry are even red or green.

Silver is used in alloy form to a large extent, particularly for coinage and silverware. Sterling as applied to silver was first used in Great Britain, and the standard of fineness was 925 per 1,000. In the United States sterling silver is usually 900 fine. The standard for coins varies greatly in different countries and in different years. In addition to silverware, silver and its alloys are used industrially to an increasing extent, one of the important uses being silver solders which give very strong brazed joints.

Ordinary solders are another important group of alloys, usually consisting of tin and lead; 40 : 60 is 40 per cent tin, 60 per cent lead; another popular composition is 37.5 : 62.5. Both of these are wiping solders which plumbers use to join lead pipes together. The American Society for Testing Materials (ASTM) lists 28 grades of commercial soft solders in their latest specification, B32-46T. The most generally used soft solder is 50 : 50.

A closely related group of alloys are the white metal alloys, consisting chiefly of lead, tin, and antimony. They are used as bearing metals and for different kinds of type metal, such as linotype, stereotype, and monotype. It is hard to conceive of a more important class of metals when we think of the great influence on the world of newspapers, magazines, and books.

One of the oldest of the bearing metals is Babbitt metal, and the latest ASTM specification

lists 14 typical and varied compositions. However, the best known of these white metal alloys is pewter, the composition of which varies considerably, but tin should predominate, with lead not over 37 per cent. Often antimony and copper are also present.

Lead is used to a great extent in the commercially pure form, but also a large tonnage of lead alloys are used in addition to those mentioned above. Among the most important are the lead-antimony alloys used extensively for battery plates.

Babbitt metal has been mentioned, and in addition to this bearing metal there are a host of others consisting of many kinds of alloys, the mere listing of which would require a considerable space. There are special bronzes of many kinds for bronze bearings, which are primarily copper and tin alloys. Many have been refined by the use of phosphorus and are known as phosphor-bronzes. Many, indeed, almost all, contain lead and are known as leaded bronzes.

When we come to the field of copper alloys, we are dealing with probably the oldest and the largest of the alloy groups. Great industries are based on the manufacture, processing, and sale of many of them, such as the extensive and widespread companies in the Connecticut Valley. These probably started with the manufacture of brass for buttons and have grown to cover every phase of the brass and bronze industry. Copper, zinc, and tin are the three basic metals, with many others being used to produce special alloys. In recent years beryllium-copper alloys have found a place of great importance.

The aluminum alloys would require an article to themselves. Some of them are familiar, especially the hard and strong alloys known as duralumin, used extensively in airplane construction. There are many kinds of this type of alloy. Almost all contain copper, manganese, and silicon, and many of them after proper heat treatment have the strength of certain kinds of steel. Many types of aluminum alloys are used for castings, including many kitchen utensils.

Castings are made of almost every kind of alloy. Toy soldiers are often made of solder. Many plumbing fixtures are made of brass or bronze, or even of stainless steel. One class of castings is becoming of increasing importance, and the alloys used cover almost the whole field. They are known as die castings. The molten metal is forced by compressed air into a closed permanent metal mold. When the metal has solidified, the mold is opened, the casting removed, the mold cleaned, prepared and closed, and again filled. Zinc alloys have proved particularly suited for such application. Telephone instrument parts, typewriter parts, automobile grids, hardware, and countless other articles are made. A typical zinc alloy contains 3 per cent copper and 4 per cent aluminum. Die castings are made from many other alloys including brasses, bronzes, aluminum, and magnesium alloys, and even cast iron.

Magnesium alloys are appearing in increasing amounts. Almost all contain aluminum, manganese, and zinc.

Nickel has only been mentioned in connection with white gold. It has many important uses as commercially pure nickel but many nickel alloys are also used. Monel metal is well known and consists chiefly of nickel, copper, and iron. The widely used electrical appliances depend on heating elements made of nickel-chrome, and nickel-chromium-iron alloys. Heat resisting alloys in general are composed largely of nickel-chromium-molybdenum alloys, and only by the use of such alloys are gas turbines and jet propulsion possible.

All the commercial varieties of iron and steel are alloys of iron. The ordinary steels are thought of as iron-carbon alloys, but practically all contain manganese and silicon as well. In addition, there are probably thousands of alloy steels, such as the special tool steels, steels for castings, forgings, and many varieties of rolled shapes. These steels are often called by the principal alloying material present: for instance, manganese steel used because of its great resistance to abrasive wear; silicon steels used largely in sheet form in transformers and electrical motors and machinery because of special magnetic and electrical properties; tungsten steels used in many kinds of tools; nickel steels used in bridges and highly stressed parts of machinery. Some of the chromium steels are now familiar in the form of stainless and heat resisting steels. One of the best-known types is 18:8, containing about 18 per cent chromium and 8 per cent nickel, but there are many other compositions to meet varying conditions of corrosion and exposure.

Metals, therefore, are not only the elements of the periodic chart, such as aluminum, copper, gold, or nickel, but also the vast and constantly increasing class of alloys.

Consulting Engineer and Metallurgist.

* TITANIUM

On Sept. 14, 1948, the commercial production of titanium metal in sponge and ingot forms of 99.5 per cent purity was announced. Initial output was 100 pounds daily and the initial price was five dollars per pound. Today titanium is one of the most important metals whose ever-increasing possibilities are attracting widespread interest. Intensive research is under way concerning its sources, chemistry, and technology, and its growing range of applications. This relatively "new" metal is already important commercially, not only as a white pigment material, but also in metallurgy, in ceramics, in the electrical industry, and as the metal itself. Metallic titanium is light, strong, tough, and noncorrosive. It has desirable properties which recommend it for many industrial applications. Very desirable gem stones have been produced from titanium dioxide.

Titanium is ninth in abundance of the elements making up the lithosphere, the ten-mile-thick crust of the earth, and accounts for 0.62 per cent of the total. It is exceeded in amount only by oxygen, silicon, aluminum, iron, magnesium, calcium, sodium, and potassium, and with the exception of these it comprises a larger proportion of the known terrestrial matter than all other metals combined, including zinc, copper, and lead, which are generally thought of as being quite common. Titanium is five to ten times as abundant as the well-known nonmetals, sulphur and phosphorus. In contrast to its widespread occurrence, however, only a few minerals bearing titanium, particularly ilmenite, rutile, arizonite, titanite, and perovskite, are known to occur in

* From *Titanium, Its Occurrence, Chemistry, and Technology,* by Jelks Bardsdale; published by The Ronald Press Company, New York.

bodies large enough to be of economic importance.

Titanium has many actual and potential uses, based for the most part upon its properties as a silvery white, light, corrosion-resistant, tough, strong metal. Among the metals available for construction there is a gap between aluminum and steel. Aluminum, with a desirably low density of 2.7, is easily formed and machined, but it has relatively low strength and is not resistant to corrosion. Iron, at the other extreme, can be alloyed to give high strength and resistance to corrosion, but its greater density, 7.87, is a decided disadvantage where weight is an important factor. Titanium, with a density of 4.5, coupled with its strength, ductility, high melting point, and noncorrosive characteristic, is the outstanding candidate to fill this gap. It combines the properties of stainless steel with those of the strong aluminum alloys and possesses certain definite advantages over both. One outstanding advantage is its high proportional limit which is comparable to that of heat-treated steels and aluminum bronze, while its density is only a little over half that of these materials. As a result, wrought titanium is in a class by itself so far as the weight of a section having a given proportional limit is concerned. Titanium would be a preferred structural material in aircraft design where a minimum weight combined with a continued high stress is important. A potential use of great importance is for making reciprocating mechanical parts in jet engines where heat and pressure are great. The metal seems almost ideal for ocean-going vessels because of its outstanding properties of lightness, strength, and great resistance to corrosion. As the cost of production is decreased, titanium will be used extensively for structural purposes. Titanium seems well suited for textile machinery where a considerable saving of power can be effected by using such a light, strong metal for high-speed spindles, spools, warp beams, and other moving parts. Another use of the future is in suspension-bridge cables. These properties of titanium may prove important in the eventual utilization of atomic energy.

The surface-hardening property of titanium gives it a definite advantage over the really light metals in the construction of parts subject to frictional wear. It seems suited for automobile pistons, because, in addition to the characteristic properties of lightness and strength, it has a coefficient of expansion a little less than that of cast iron which is ordinarily used for cylinders. Combination of stainlessness, high proportional limit, and low modulus makes it an ideal material for springs, and its use should make possible the construction of greatly improved spring balances and watch springs. Its properties also recommend it for use in tool mountings where a certain amount of give is desirable to prevent breakage. X-ray diffraction tubes with titanium targets are in the development stage. Rubbing titanium metal against a hard surface often produces a smear which is difficult to remove, and this characteristic is employed for a variety of purposes, including the production of very stable high electrical resistance glass, simply by marking the surface with a titanium point. Such smears can be used to coat materials with a metallic film and to etch glass without the use of hydrofluoric acid. The really large-scale use of titanium seems to depend only on its availability in suitable form at a price in line with the common metals such as iron and aluminum. It would be a notable exception to technological progress if titanium, with such desirable properties, failed to be an important engineering metal of the future.

Bibliography.—American Society for Metals, *Metals Handbook* (Cleveland 1939); Deming, H. G., *General Chemistry* (New York 1944); American Society for Testing Materials, *Book of Standards* (Philadelphia 1946).

METAMERISM, *in chemistry,* that variety of isomerism in which chemical compounds have identical percentages of composition and also like molecular weight. When two or more chemical compounds have the same empirical formula, but consist of different radicals united by an element (or a radical) that is common to them all, the compounds are said to be "metameric," and the property itself is called "metamerism." The common element that unites the radicals is usually oxygen or nitrogen. Good examples of metamerism are afforded by the compound ethers and amines. Dipropyl ether, methyl-amyl ether, and ethyl-butyl ether, for example, all have the empirical formula $C_6H_{14}O$; but dipropyl ether contains two propyl radicals (C_3H_7), methyl-amyl ether contains one radical of methyl (CH_3), and one of amyl (C_5H_{11}), and ethyl-butyl ether contains one radical of ethyl (C_2H_5) and one of butyl (C_4H_9); the two radicals being connected, in each case, by an oxygen atom. The structural formulae of these respective compounds are therefore as follows:

Dipropyl ether.	Methyl-amyl ether.	Ethyl-butyl ether.
$\begin{matrix}C_3H_7\\C_3H_7\end{matrix}\!>\!O$	$\begin{matrix}CH_3\\C_5H_{11}\end{matrix}\!>\!O$	$\begin{matrix}C_2H_5\\C_4H_9\end{matrix}\!>\!O$

The following amines, which all have the empirical formula C_3H_9N, illustrate metamerism in which nitrogen is the connecting element:

Propylamine	Methylethylamine	Trimethylamine
$N\left\{\begin{matrix}C_3H_7\\H\\H\end{matrix}\right.$	$N\left\{\begin{matrix}CH_3\\C_2H_5\\H\end{matrix}\right.$	$N\left\{\begin{matrix}CH_3\\CH_3\\CH_3\end{matrix}\right.$

Metamerism may be regarded as a species of accidental isomerism. When metameric compounds are treated with reagents which destroy the bonds between the constituent radicals and the atoms (of oxygen or nitrogen) by which they are united, the several members of the metameric group that is so treated yield totally different products, because they contain totally different radicals.

In zoology, metamerism signifies the repetition of parts in an organized body, as in segmented worms, certain vertebrates, arthropods and lobsters. The meres or segments fall into two classes, those in which the meres repeat with no apparent change and those in which there is modification as the series progresses.

METAMORPHIC GEOLOGY. The process by which one rock is altered into another is known as metamorphism, and the branch of geology which treats of the cause and nature of this change is known as metamorphic geology. See also ROCK CLEAVAGE, METAMORPHISM; METAMORPHIC ROCKS; ROCKS.

METAMORPHIC ROCKS, those rocks of either igneous or sedimentary origin which

have undergone sufficient heat and pressure to be altered into a different kind of rock. In this way limestone becomes marble, sandstone is changed to quartzite, and shale passes over into slate or schist. Metamorphic rocks are usually most abundant in regions of mountains where the rocks have undergone much folding and compression. See MARBLE; QUARTZITE, METAMORPHISM, and the section on *Metamorphic Rocks* in the article on ROCKS.

METAMORPHISM. When rocks of either igneous or sedimentary origin undergo sufficient change so that they largely develop new minerals, and become other types of rocks, they are said to be metamorphosed, and the process is called metamorphism. Such changes may be brought about in many ways. One of the most familiar is the process of weathering (q.v.) by which the minerals of a granite, for example, undergo alteration, the quartz remaining behind as quartz, the feldspar altering chiefly to clay, and the soluble lime, magnesia, potash and soda going to the sea, the first two to form limestone, the latter to produce the salt of ocean water. Thus the complete weathering of a granite and the sorting of the products finally results in the formation of shale, sandstone and limestone. This phase of metamorphism is called katamorphism. It is produced by the atmospheric agencies and results in simpler mineral compounds and rocks.

If on the other hand, a sedimentary rock be subjected to intense heat or pressure, or both, the minerals present recombine to form new minerals, usually more complex, which are better suited to conditions of heat and pressure. This phase of metamorphism is usually called anamorphism. In general usage, the term metamorphism is commonly restricted to what is here termed anamorphism, that is, to those changes due to heat and pressure. The term metamorphic rocks (q.v.) is wholly restricted to rocks which have undergone changes of anamorphic nature. Thus, for example, a shale which has resulted from the weathering of a granite, though it has undergone metamorphism in the broadest sense, is not considered a metamorphic rock.

The heat and pressure which cause metamorphism may be produced by compression and folding over large areas, in which case there is said to be dynamic or regional metamorphis; or they may be due to the intrusion of large masses of highly heated igneous rock (magma), in which case there is said to be contact metamorphism.

Regional metamorphism results largely from pressure, heat is only incidental. The most common minerals to result are those which are flat like mica (q.v.), or elongated like hornblende (q.v.). These naturally develop in parallel arrangement with their smallest dimension opposed to the pressure, that is their larger dimension is at right angles to the compression. This seems to be the easiest way in which such minerals can develop. As a result of this arrangement, such rocks split more easily in certain directions, just as wood splits parallel to the grain. This is called cleavage, and is best manifested in slates (q.v.) and schists (q.v.).

Contact metamorphism, on the other hand, is due largely to heat; pressure plays a less important part. The changes at a contact may be of several types. The rocks may be simply baked or they may be actually fused. The minerals present may recombine to form new minerals. There may be much new mineral matter actually added from the igneous mass, as in the case of contact ore deposits, where ore minerals make up a large part of the contact rock. Or the heat of the igneous mass may drive off substances already present, especially water and carbon dioxide. At most contacts these processes have probably all played a part. The intensity of the metamorphism and the width of the altered zone depends on several factors, such as the size and temperature of the igneous body, the amount of the water or steam present, and the resistance of the enclosing wall rock. A quartzite (q.v.) wall rock may be little changed, while a limestone (q.v.), because of its greater solubility, may be profoundly altered. An abundance of steam aids in producing a marked effect, since it readily works its way out through pores in the rock, carrying much mineral matter. Alteration produced largely by steam or hot water is termed hydrothermal metamorphism. Changes produced by ordinary circulating waters are sometimes termed hydrometamorphism. See CLEAVAGE; GEOLOGY; METAMORPHIC ROCKS; ORE DEPOSITS. Consult Van Hise, C. R., 'A Treatise on Metamorphism,' (U. S. Geological Survey, Mon. XLVII, Washington 1904); Leith, C. K., and Mead, W. J., 'Metamorphic Geology' (New York 1915); Leith, C. K., 'Rock Cleavage' (U. S. Geological Survey, Bull. 239 Washington 1905); Grubenmann, U., 'Die Crystallinen Schiefer.'

METAMORPHOSES. Ovid's 'Metamorphoses,' or 'Transformations,' were published in the year 8 A.D., when the poet was 50 years old. They were finished just before the issue of the imperial order which consigned Ovid to banishment at Tomi on the Black Sea for the remaining eight years of his life. In consternation at the punishment which had overtaken him, he elsewhere tells us that he consigned to the flames his own copy of the poem. But other copies were already in the hands of his friends; it is to these that we are indebted for the preservation of the work.

The poem consists of 15 books in hexameter verse descriptive of the various transformations through which various men and women were conceived to have gone. In the conception of the Greeks almost every river, rock, spring, tree and mountain had attached to it the legend of some such wonderful metamorphosis. Thus the poplar trees are the weeping sisters of Phaëthon; the laurel is Daphne; a spring is Arethusa; etc. The source of this multitude of transformations found in ancient legends is doubtless to be sought in the ancient conception of inanimate objects as animate. Each rock and tree and hill with the Greeks and Romans was a personal being endowed with a spirit. Thus the poplar trees and the fountain and the laurel were regarded as animate to start with; they had not merely become so by receiving the souls of certain men and women. To the vivid imagination of the Greek the waving form of rustling tree or shrub, the moving mass of bubbling or falling water suggested life and individual spirit. The problem was to account for the present form. The inanimate objects represented as the result

of transformations had, accordingly, been conceived as animate from the outset, and the stories of their transformations are merely later inventions devised to account for their primitive conception as personal beings.

Some 250 of the stories belonging to the body of Greek and Roman legend and mythology receive treatment in Ovid's work, which thus becomes a fairly complete treatise on the classic myths. Among the most important of these are the stories of Deucalion and Pyrrha, Daphne, Phaëthon, Cadmus, Semele, Echo, Narcissus, Pentheus, Pyramus and Thisbe, Ino, Perseus and Andromeda, Niobe, Procne and Philomela, Medea, Theseus, Scylla, Daedalus, Philemon and Baucis, Hercules, Orpheus, Adonis, Thetis.

Relatively little space is devoted to the actual metamorphosis in Ovid's poem. The transformation is simply the culmination of a story, generally one of some length. Thus after detailing with great fullness the adventures of the ill-fated Phaëthon with the horses of Phœbus, the poet finally concludes by briefly recounting the transformation of Phaëthon's mourning sisters into poplar trees. So with the other stories; the transformation holds an inconspicuous place, being simply the feature common to all. The different narratives are woven together most ingeniously. There is no break. Each is connected with the preceding and following by some natural link, so that we have one continuous narration from the transformation of the stones of Deucalion and Pyrrha into men to the transformation of Julius Cæsar into the comet which appeared after his death. By the poet's fiction, therefore, the treatment is made to assume the illusion of chronological sequence. In the last books Ovid approaches the legends of the Trojan cycle and of early Roman history, gradually bringing the reader to the events of his own day.

With great artistic skill the poet varies the manner of presentation. The larger part of the stories are his own narration, but monotony is avoided by resort to other devices. Thus a number of legends are put in the mouth of Orpheus. Others are recounted by the three daughters of Minyas to while away the time as they sit at their spinning.

The 'Metamorphoses' is Ovid's masterpiece and has always enjoyed high favor. The poet's own faith in his work is indicated by the concluding verses of the final book, in which he gives free expression to his confidence in the immortality which he feels it has won for him: «Over the stars his name shall soar; as far as the Roman dominion reaches his work shall be read, and it shall live for all eternity.»

The most recent translation is by F. J. Miller in the Loeb Library.

CHARLES E. BENNETT.

METAMORPHOSIS IN ANIMALS, the changes which in many animals take place between the time of birth and maturity. The causes are most probably changes of habitat, of seasons, of food and the acceleration in growth resulting from the approach of sexual maturity. Familiar examples are the change of the caterpillar into the butterfly, of the tadpole into the toad or frog.

In the frog and toad, metamorphosis is complete and thoroughgoing. The embryo on hatching from the egg has a large head and body, but no tail; in a few days its tail grows out and it becomes a tadpole, when it is fish-like, but without fins or limbs. With the growth of the tail, the external gills appear, and the mouth is formed, while the intestine becomes very long and closely coiled. The mouth is armed with horny, comb-like plates, on which develop great numbers of microscopic teeth, which are shed continuously. In changing from the tadpole to the toad or frog, the body, including the skull and rest of the skeleton, and the viscera are made over anew; the external gills disappear as the lungs develop, the true teeth appear in the jaw, the intestine becomes short and straight, and the creature instead of nibbling decaying leaves or dead animals feeds on living snails and insects. Soon the tail becomes absorbed, finally the hind legs grow out, the gills disappear, the front legs bud out and the adult form is attained. While most amphibia pass through such a metamorphosis, in a few forms, owing to the absence of water or other changes in the environment, development is direct, the metamorphosis being suppressed. Metamorphosis may be retarded by cold and shortened by hunger, and in the amphibians or in insects the changes are greatest in modern and specialized forms, as frogs and toads.

The metamorphosis of the butterfly is the most complete of those of all insects. The life of the insects is divided into four stages, that is, the egg, larva, pupa and imago or adult. During the larval and pupal periods the insect is, so to speak, a different animal from the adult. The caterpillar is provided with big jaws and eats voraciously; in shape and structure it differs widely from the winged adult. The pupa or chrysalis is also different from the larva, and also from the imago; it takes no food and rests almost motionless. On the other hand, the butterfly has no jaws, while its maxillæ form a long coiled-up tongue, beautifully adapted for probing the corollas of flowers. Though these changes appear to be sudden, the internal alterations of cells and tissue which lead to them are gradual. From one to three days before assuming the pupa state the caterpillar becomes restless and stops eating. If a spinner it spins a cocoon, or if not it enters the earth to undergo its transformation into a chrysalis, or if a larval butterfly it attaches itself to some fixed object, as a tree or fence. Profound changes now take place in the mouth-parts as well as the nervous, muscular and other systems of internal organs.

But the changes are most marked in the flesh flies and their allies. At the end of the maggot stage, the internal organs are destroyed, breaking up and forming a creamy mass, and the appendages and wings arise from minute internal masses of cells called «imaginal buds» which are present in the maggot. The body is thus entirely made over anew. But while the process of destruction of the larval organs and appendages goes on, there is also a constructive process, during which the organs of the adult state are being built up. It is thus evident that the sharp division of the life-history of the insect into larval, pupal and imaginal stages only applies to the external surface of the body. The internal processes of development, on the other hand, form a continuous series of transformations between which is no sharp line of demarcation. Yet as a whole the form of the

larva, pupa and imago are kept distinct in adaptation to their separate environments and habits.

Hypermetamorphosis.— This name is applied to the changes undergone by certain beetles (*Meloë, Stylops,* etc.), in which there are more than the usual number of larval and resting or pupal stages. Thus, in the common oil-beetle (*Meloë*) and in the blister-beetles (*Epicauta*), the larva hatches as a minute, active, triungulin creature which is a parasite in bees' nests, feeding on their eggs; it passes into a second larval stage, when it is grub-like, inactive, the body being thick, cylindrical, soft and fleshy; this passes into a motionless semi-pupa, and thus after molting assumes a footless larval form; it then transforms into a true pupa like other beetles. There are thus four distinct larval stages, besides the pupa and beetle. Now these stages correspond to the habits and food of the young beetle, and these supernumerary stages and marked changes of form are evidently due to changes of environment, of habits and of food, resulting in the atrophy of limbs in certain stages. This throws light on the causes of metamorphism in general.

No Distinct Metamorphosis in the Primitive Insects.— The wingless insects (*Synaptera*) do not pass through a metamorphosis. And it appears, as first suggested by Fritz Müller, that the habit of metamorphosing is an acquired one. Thus in the more primitive winged insects, such as the cockroach, grasshopper, bugs, etc., metamorphosis is incomplete, the young differing mainly from the adult in not having wings. Also the most primitive arthropod animals, such as the horse-foot crab (q.v.), the spiders and myriapods, pass through no metamorphosis.

Metamorphosis in the Lower Animals.— The more specialized cœlenterates (*Medusæ*), the echinoderms, mollusks and crustaceans, as well as many worms, undergo remarkable changes of form. (See LARVA). The larva of the marine annelids is a top-shaped ciliated creature (*trochosphere*) entirely different from its parent. The marine mollusks pass through a larval condition (*religes*). The young of the sea-urchin, star-fish and holothurians differ remarkably from their parents in being bilaterally symmetrical, transparent and free-swimming; they serve as scaffoldings from which the body of the adult is developed. The shrimps, etc., are hatched in a nauplius or six-legged form, and crabs in a zoëa form.

METAPHOR, a figure of speech expressed in a single leading word; a similitude — for example, "The man is a lion," is a metaphor; "The man is as bold as a lion," is a simile. Metaphor is an ideal characterization or illustration which may be affirmed by one mind and denied by another, or affirmed and denied by the same mind at different times; it is a kind of comparison in which the speaker or writer rejects the circumlocution of the simile and attains his end immediately by establishing the identity of his illustration with the thing spoken of. It is thus of necessity, when well conceived and expressed, graphic and striking in the highest degree, and has been a favorite figure with poets and orators and makers of proverbs in all ages. Even in ordinary language the meanings of words are in great part metaphors; as when we speak of an *acute* intellect or a *bold* promontory: all such words are *in metaphor,* and the *language* may be called *metaphorical.*

METAPHOSPHORIC ACID. See PHOSPHORIC ACID.

METAPHYSICAL DETERMINISM. See DETERMINISM.

METAPHYSICS (from Gr. *Meta ta phusika,* "after physics," alluding to the position of Aristotle's treatise on metaphysics in his works). Metaphysics and epistemology (q.v.) are the twin sciences of the nature of reality and of our knowledge thereof. Metaphysics seeks for the criteria of being, epistemology for those of truth. As the truth is generally conceded to possess some peculiarly intimate relation to reality which is not found in the case of error, and as our sole avenues of access to reality are those of experience, be it sensory, rational, emotional or volitional, the boundary line between epistemological and metaphysical opinions is of the most obscure and wavering nature, so that a separate study of the two disciplines is exceedingly unprofitable. We shall accordingly shift our standpoint continually from that of one science to that of the other.

Metaphysics is not a subject which one can study or refuse to study at will; whether it is explicit or not, there is always some criterion of truth, of reality, that permeates our barest common sense. This may be metaphysically inadequate, but must be metaphysical. When I draw a distinction between a dream and an experience of waking life, between a truth and a lie, between a fact and an error, I am drawing a metaphysical distinction. When a physicist reduces the table before him to a vast aggregate of electric charges, or asserts the basic identity of time and space, or interprets light a transverse electromagnetic vibration, he is nothing if not metaphysical, for he is drawing a distinction between the appearance of things and their underlying reality. Even those who claim to be agnostics or sceptics in the professor's chair are tainted with metaphysics in their daily life, for the only agnosticism, the only scepticism which can free itself from all blemish of metaphysics is an agnosticism, a scepticism so complete that it does not even tentatively maintain any criterion of reality or unreality, of truth or falsity.

We have accordingly three stages of metaphysics to discuss: (1) the metaphysics of common sense; (2) the metaphysics of the natural scientist; (3) the metaphysics of the technically trained philosopher.

(1) The Metaphysics of Common Sense. — The average philosophical layman, be he educated or not, believes that the wall he sees in front of him, the cane that he holds, the song that he hears are real, with an immediate and underived reality. He is confident that the wall, the cane, even the song would be the same with nobody to experience them. He is also confident that he exists, and that his existence is utterly independent of any experience he may have. Now, this view that the object is out there and I am in here, and that seeing is something which needs no analysis (for so the layman believes), works remarkably well providing I only see things that are so. It is, however, clear that in my dreams and other illusions I frequently see things that in some

manner are not so. If seeing is an immediate relation between me and my object, what is my object when I dream of something which, in every common-sense interpretation of the words, does not exist?

This is obviously the highest common factor of metaphysics and epistemology, for it unites the fundamental questions of the two sciences, the question of truth and that of reality. What is more, it is in essence the one cardinal problem of both sciences, the great problem of error. The problem of error may be approached from two different angles, according as there are supposed to be real entities which form the objects of erroneous experience, or no such entities at all. In the latter case, experience must be interpreted as not essentially a subject-object relation. As we shall see, practically all the earlier modern philosophers hold that erroneous experiences have objects. The second alternative is indicated in Spinoza and appears in the philosophies of Kant and Hegel.

(2) The Metaphysics of Natural Science. — Of course, science as such can have no peculiar metaphysics, for the truth is essentially one — unless we adopt the pragmatist attitude — and cannot be changed into a falsehood merely by looking at it through the spectacles of a particular discipline. Nevertheless, there is a certain conventional metaphysics which may be read between the lines of the majority of scientific textbooks, the habitat of which is the laboratory and the specimen-box. Though this may be traced to the Greeks, it owes its incarnation in its present avatar to Descartes and Locke. Both these writers, who are conventionally called dualists, since they believe in the essential distinctness of mind and matter, are really rather what one might name ternarists, inasmuch as they posit between the self and its objects a third class of entities, the ideas, by the mediation of which the mind or self is aware of the outer world. Dreams differ from true waking experiences in that the ideas they contain have no realities corresponding to them. Modern science has turned the real universe into a world of movements of material particles, or of electric charges, without any intrinsic color or sound, and has relegated these latter qualities to the realm of ideas. The physical correlates of these ideas are, of course, particles or charges in motion. By the mediation of the nervous system these particles or charges and their movements are supposed to produce certain alterations in the brain — Descartes considered that they were in the pineal body, while the advance of modern science has placed them in the cerebral cortex — which have as invariable concomitants certain ideas or ideational processes. It is these that form the sole direct object of human inspection.

This theory is perfectly successful in explaining error, but remarkably inadequate in accounting for anything else — any knowledge, that is, which is not a mere accidental blundering belief. The situation is quite analogous to that of a man gazing at the cover of a book and trying to know what is inside. This knot or rib in the cloth *may* cover an exposition of this or that theory, but if the book is permanently locked up, and is opaque, we can never know this. We consequently find that at the very beginning additions and modifications were made in the theory. These, however, belong to

(3) The Metaphysics of the Technical Philosopher. — Modern philosophical tradition may be said to commence with Descartes. Accordingly, he is the first man with whom the metaphysical issues of the present day receive the division and treatment with which we are familiar. We have seen that he divided the world into separate realms, apparently of mind and matter, but really of soul, matter and ideas. Nevertheless, he saw the difficulties of the problem of error and tried to give it a more adequate solution than that pertaining to the conventional philosophy of natural science. As the founder of modern mathematics he tried to introduce mathematical criteria of truth into metaphysics, and so he starts with the proposition, "I think, therefore, I am," the denial of which he regards as self-contradictory in the same sense in which "2 has a rational square root" is self-contradictory. Having thus obtained the existence of the self, he goes on to demonstrate that God exists: "I have an idea of a most perfect Being, and this idea can only come from the Being with the one perfection my idea lacks, that of existence." Once he has got this Being, Descartes asserts that our knowledge of matter receives its guarantee in the honesty of God. This relieves the difficulty we encountered in the metaphysics of the scientist, the difficulty of bringing ideas and their objects into relation, but it is not by any means completely satisfactory. If God is honest, how can we make blunders? By failing to have our ideas clear and distinct, says Descartes. But how can an honest God permit vague ideas? This involves us in the interminable and fruitless controversies concerning the relative power and goodness of God which were so characteristic of the mediæval schoolmen at their worst.

Descartes' philosophy thus involves a *Deus ex machina*. His followers, without exception, laid far more emphasis on this phase of his philosophy than he himself. In the systems of Geulincx and Malebranche, God becomes the agent causing every change in mind and matter, who for each change in the one wills that there shall be a corresponding change in the other. From this Occasionalism it is but a step to the monism of Spinoza, for whom mind and matter are but two among an infinite number of aspects of the one reality, God. From another standpoint, the entire world is the content of intellection, without the mediation of the Cartesian and Lockean "ideas." Spinoza retains the logical, mathematical, intellectualistic standards of truth and knowledge which were set up by Descartes, but he has also a mystical, emotionalistic view of the nature of reality, in that he believes that this is most truly perceived through the Intellectual Love of God.

The *Deus ex machina* survives in the views of the next great continental philosopher, Leibnitz. Instead of the two substances, mind and matter, of the Cartesian tradition, he supposes an infinity of substances, the monads, all partaking to some extent of a mental nature. In place of calling upon God's continual intervention to keep these experiences in accord with the facts, Leibnitz supposes that at the Creation the Lord foreordained that all these many experiences should keep time, just as two perfect clocks, wound up and set together, will agree

on all subsequent occasions until they run down. It will be seen that the problem of error appears in the philosophy of Leibnitz almost in its Cartesian form.

Leibnitz regarded the monads as possessing ideas of various grades of clearness and distinctness, and believed that matter was made up of those with the vaguest ideas. Because he considered matter to be of the nature of mind, Leibnitz is called an idealist, and is classed together with Berkeley, whom we shall next consider. By observing the vast distance that separates the philosophies of these two men, it will be possible to see how little content inheres in this term, which, with its contradictory realism, has been singled out by a certain American philosophical school as the index of a grand dichotomy of all philosophical systems.

Berkeley belongs to the British empiricistic tradition. His immediate philosophical ancestor is Locke. Unlike Locke, however, Berkeley saw that no object not directly given can furnish a test of empirical reality, nor an aid in its explanation. Accordingly, his world consists of selves and their ideas or sense-data. This does not mean that he rejected natural science, but that he insisted that all its propositions were capable of expression in terms of ideas. Such ideas as are not immediately given to any person he considered to reside in the mind of God, one of whose functions it becomes, to put it crudely, to watch things when nobody is looking and to see that they do not vanish away. However, it will be noticed that an idea in the mind of God which is not experienced by us is as inert, remote and useless from an explanatory point of view as a bit of matter. Furthermore, the self apart from its ideas does not appear to play any great part in knowledge. Given an experience, nothing more seems to be added by the adjunction of the self. For these reasons, the next successor to the British tradition, David Hume, rejected both the Berkeleyan matter — thinking God and the soul as a specific entity, and interpreted the world purely and simply as an aggregate of sense-data.

We thus see the contrast between the natural-scientific and the Humian view of the universe; for the naïve scientist, a bit of experience is really an aggregate of atoms in motion, whereas for Hume an atom in motion would have to be interpreted in terms of bits of experience. Unfortunately, Hume possessed neither the scientific knowledge nor the logical mechanism to carry out this process in any but the crudest and most schematic way, and his philosophy of space, time and causality is in detail as bare and inadequate and unsatisfactory as any yet devised. Recently, however, Bertrand Russell, who is essentially a Humian in spirit, though he adopts the independent nature of the soul as at any rate a plausible hypothesis, has developed a treatment of these subjects, and of many other allied ones, which is at once scientific and at bottom after the manner of Hume. Matter, for instance, is treated as the system (Hume would have erred by saying "the sum") of its appearances; an atom or electron becomes a class of sense-data or a relation between them, or something of this general nature. The scientific analysis in terms of atoms and electrons is recognized as valid, but as based on a deeper analysis into the experiences out of which atoms and electrons are artefacts.

This recrudescence of British empiricism, however valid its opinions and valuable its results may be, is off the main stream of philosophical development during the latter part of the 18th century and the entire 19th. This main stream has its source in Kant, who, to continue the metaphor, marks the junction of the currents of British and of Continental thought. What is most distinctive in the thought of Kant is his definite and final occupation of the standpoint of epistemology, as the true ground for the determination of the problems of metaphysics. Now in so doing, Kant is making thought the measure of reality, and this seems to be only repeating the judgment of Spinoza. But there is a great difference. Kant declines to accept Spinoza's doctrine of thought and reality. The real is more than the content of thought. In fact Kant returns to the ancient intuition of thought as formal, and the real as in some sense its correspondent. This was also the tradition of Locke and his school, from which Hume departed, as we have seen, with a result that is often called scepticism. Now the history of Kant's thought shows that, while he clung to the belief in the mere formal character of thought, his tendency was also strongly in the direction of scepticism. Moreover it was on account of his failure to completely achieve what he calls his Copernican revolution, and which was in fact a reaction toward a constitutive doctrine of thought, that he was never able, during the whole of his critical period, to reach a satisfactory conception of the relation of thought to reality. Had Kant completely achieved the mental revolution he proposed, the result would have been, that in epistemology he would have asserted the doctrine of Spinoza, the identity of the real with the content of thought. The knowable world would thus have been identical with the real world and Kant would have escaped the dualism between knowledge and reality into which he actually fell. Kant also denies the universality of thought; at least in the ontological sense. The thought that functions epistemologically is my human relative thought which can only pronounce judgments that are subjectively valid for me, but have no ontological value for reality. The Kantian metaphysics is a corollary from his epistemology. What Kant calls critical idealism is first an epistemology, secondly a metaphysic. As an epistemology it teaches that my thought is constitutive for me; that is, that its content is valid for my subjective connation. It gives me a world, in other words, in which I can work out the practical issues of my life, but it does not give me the world of real things in themselves with respect to which my attitude must be one of renunciation. As a metaphysic critical idealism simply carries its program out in the field of ontology. The presumption of the identity of what is thought with the real cannot be carried out objectively. Kant's metaphysics is therefore necessarily negative. Thought is able to complete itself ontologically, it is true, but the ideals it reaches have no other than subjective value. Their hypothetical content can never be identified with the real, and the Kantian is per force obliged to represent the whole ontological region as an indeterminate X and to look for

the satisfaction of his wants to extra-metaphysical forces. These he finds in the domain of ethics.

In Hegel we have also an example of a thinker who approaches metaphysics along the epistemological way. But Hegel is a much more thoroughgoing thinker than Kant. He starts no doubt with the Kantian traditions in mind and his first great task, the development of his logic, is formal. But Hegel is not a formal thinker, in the sense that he divorces content and form. Thought is formal. This Hegel is not afraid to confess, but it is also ontological. At the same time there are no outlying realities, like the Kantian things in themselves. How is this? Are we to have the spectacle of a lapse into Spinoza? Our apprehensions are ungrounded, for Hegel asserts calmly that the form creates the content. Hegel asserts the identity of thought and reality in the sense that the real is, and is only, what the thought thinks it to be. It is the real by virtue of the thought thinking it to be. This sounds like a dangerous kind of subjectivity, till we learn that by thought Hegel means, not my thought or yours, as simply my or your intellectual function, but the thought that is universal and that thinks the universal. So much for Hegel's epistemology. In Hegel's system epistemology and metaphysics are simply two aspects of the same thing. In epistemology we have the system logically conceived; that is in view of the process which the finite thought of the individual must pass through in order to apprehend it; whereas in the metaphysics we have the system presented in its unity as a self-completing whole. Epistemologically the dialectic is the movement by which results are achieved; metaphysically it is the Divine Spirit of the system as a whole. Error is accounted for precisely by the disparity between individual and universal thought.

One of the most remarkable aspects of the metaphysics of the past century is the strong voluntaristic or emotionalistic trend which is to be observed among writers of the most different philosophical ancestry. Schopenhauer, though in many ways a follower of the Kantian tradition, interpreted the course of events as the manifestation of a world-will, which performs the functions of the Kantian thing-in-itself. This will manifests itself in man as will in the ordinary sense, while in matter it is seen as force. A view which displays an analogous voluntaristic or rather activistic trend, though in every other respect most unlike that of Schopenhauer, is pragmatism, the chief exponent of which was the American philosopher, William James. This view states that the truth of a theory or the reality of a system is not merely determined but constituted by what is in some sense the ease with which it can be applied and the value of the results of this application. A similar position is that of Henri Bergson, who maintains that the analysis of science yields us only half-truths, while the real nature of the world is shown to us by intuition, which exhibits it to us as the working of a certain vital impulse.

There is no metaphysics at the present time which can lay claim to a general acceptance. The 19th century domination of all philosophy by the memories of Hegel and Kant is passing away, and the tendency of worshiping these great men as philosophical demigods is wellnigh extinct. Their followers, numerous though they are, must dispute their realm with the modern critical adherents of the British tradition, armed with modern logic, mathematics and science, and with the pragmatisto-Bergsonian tendency.

Before closing this article, let there be a word of caution to the reader against that facile metaphysical criticism which depends on labels. We have already seen that the line of cleavage between idealism, or the view that all things are either thoughts or their thinker, and realism, which asserts the existence of other entities, does not of itself mark one of the great philosophical dichotomies; Berkeley, the first typical British idealist, and Leibnitz, the idealist of the Continent, both, fall into the epistemological difficulties which are generally accepted as characteristic of realism, in that the problem of the relation between the knower and the known remains in what is essentially the Lockean or Cartesian stage. The distinction between spiritualism, which is almost a synonym of idealism, is that it regards matter as constituted of psychical material, and materialism, which analyzes mind in terms of matter, is similarly not a touchstone to the real nature of the views which it denies. The only really satisfactory method of metaphysical criticism is by the careful individual analysis of each philosophical system according to its own concepts. See EPISTEMOLOGY; PHILOSOPHY; PHILOSOPHY, HISTORY OF; and the articles on the individual philosophers mentioned.

NORBERT WIENER.

METASOMATISM. According to the United States Geological Survey, "Metasomatism may be defined as the process by which, through chemical interchange, a mineral or aggregate of minerals undergoes partial or

complete change in chemical constitution." More simply stated, metasomatic ore bodies are formed when the ore substance replaces the rock particle by particle, instead of filling already existing cavities. Replacement is frequently used as a synonym for metasomatism, and ore bodies so formed are usually called replacement bodies. Replacement, unfortunately, is used loosely by some writers, to indicate cavity filling, and these authors use the term metasomatic replacement in the same sense in which others use the term metasomatism. According to the most careful usage metasomatism and replacement are synonyms, and apply to ore bodies replacing the wall rock particle by particle. "Metasomatic replacement" is then pleonastic.

METASTASIO, Pietro, pē-ā'trō mā-tās-tā'zē-ō (properly PIETRO TRAPASSI), Italian poet: b. Rome, 13 Jan. 1698; d. Vienna, 12 April 1782. His poetical talents were early displayed in improvisations, and often he drew about him a crowd to listen to some versified narrative. The jurist Gravina, who thus accidentally became acquainted with his talents, took him under his protection, called him (by an Italianized translation of his name into Greek) *Metastasio,* paid great attention to his education, and on dying in 1717 left him an estate of $20,000. On 15 April 1718 he was received into the Arcadian Academy with the name of Artino Corasio, and in 1720 entered at Naples the office of the attorney Castagnola, who discountenanced literary work, and kept him severely to the law. He wrote anonymously 'Gli Orti Esperidi' (1722), but the authorship was soon revealed, and Metastasio left the lawyer's office, studied further, and wrote a series of musical dramas, or melodramas in the true sense, which were set by leading composers and given with great success. In 1730 he settled in Vienna as court poet, and there in 1730–40 wrote his best works, 'Demetrio,' 'Issipile,' 'Demofoonte,' 'La Clemenza di Tito,' 'Attilio Regolo.' In the consideration of Metastasio's rank as a poet, his work must be viewed not absolutely, but with regard to its original environment, as done in collaboration with a composer, and rendered by great artists. He wrote, too, for the predominantly vocal system of Italian musical drama; and with this his poetry fell into comparative neglect. His writings have been praised by so good a critic as Symonds for excellent versification, ease of diction, effective simplicity of construction and frequent imagery of the highest rank. His lyrical verse and criticisms are also of value. The best collected edition of his works is that of 1780–82 (Paris). Consult Massafia, 'Pietro Metastasio' (1882); also Lee, 'Studies of the 18th Century in Italy' (new ed., 1908).

METASTASIS (1) *in medicine,* a change in the seat of a disease, attributed to the translation of morbific matter to a part different from that which it had previously occupied, or to the displacement of the irritation. Mumps is a disease peculiarly liable to induce metastasis. In adult males the inflammation often goes to the testicles, producing orchitis, and in adult females to the breasts or ovaries, in the latter case ovaritis. Mastoiditis often results in similar shifting of the inflammation by the travel of blood clots, and the inflammation may reappear in any of a dozen places. (2) *In botany,* a change produced upon a substance designed for the nutriment of a plant, to make its assimilation more easy. Thus, when the starch formed in the leaf of a potato has to be transferred to the tubers as a depot of nutritial material, it is first changed into a soluble substance — glucose. See METABOLISM.

METATE, the stone implement on which grain and other substances, more especially corn, were ground before the discovery of America and are still ground throughout the territory of the United States occupied by the Pueblo Indians, and in Mexico, Central America and much of South America, more especially the west coast. See MORTAR.

METAURUS, mę-tâ'rŭs, or **METAURO,** mā-tow'rō, Italy, a river in the Marches, which flows northeast past Saint Angelo in Vado, and falls into the Adriatic, southeast of Fano; total course, about 50 miles. It is noted for the victory gained by the Romans under the consuls Claudius Nero and Livius Salimator near its banks over the Carthaginians under Hasdrubal 207 B.C.

METAVOLTINE. A sulphur-yellow mineral occurring in aggregates of hexagonal scales at Madeni Zakh, Persia. Dichroic. Hardness, 2.5; specific gravity, 2.53; composition: Sulphuric acid, 46.90; sesquioxide of iron, 21.20; protoxide of iron, 2.92; potash, 9.87; soda, 4.65; water, 14.58. Much of the mineral called misy belongs to this species.

METAYER, mĕ-tā'yĕr, Fr. mā'tĕ'yā' (L. Latin, *medietarius*), a name given in France to the cultivator of a *métairie* or farm who reserves for himself one portion of the produce as the price of his labor and gives the proprietor the other, which represents the rent of the land after deducting what is necessary to keep up the stock. The greater part of the center and south of France, and almost the whole of Italy, is cultivated by métayers, who are in general upright, economical and industrious. This system of farming on shares, usually half and half, is extensively practiced in the southern United States where both white and negro share croppers cultivate tobacco and cotton acreage. The introduction of modern farm machinery and the population trend to urban life will no doubt reduce the number of tenant farmers. See AGRICULTURE IN THE UNITED STATES; COTTON CULTIVATION IN THE UNITED STATES—*Share System.*

METAZOA, one of the two great sections into which Huxley divides the animal kingdom, the other being the Protozoa. The Metazoa embrace all animals composed of more than a single cell, that is all that develop through eggs or ovum. The *Porifera* or sponges are the lowest of the Metazoa. See ANATOMY, COMPARATIVE; PROTOZOA.

METCALF, William, American steel manufacturer: b. Pittsburgh, Pa., 1838; d. 1909. In 1858 he was graduated at the Rensselaer Polytechnic Institute, Troy, N. Y., and from 1860 to 1865 supervised the manufacture of Rodman and Dahlgren guns at Fort Pitt, Pittsburgh. In 1868 he entered the steel manufacturing field and in 1898 organized the Bræburn Steel Company, of which he was president for 11 years. It is said that Metcalf made the first crucible steel in America. He was president of the

American Institute of Mining Engineers in 1881 and of the American Society of Civil Engineers in 1893. He published *Steel—A Manual for Steel-Users* (1896).

METCALFE, Sir Charles Theophilus, 1st Baron, English Indian and colonial administrator: b. Calcutta, Jan. 30, 1785; d. Malshanger, near Basingstoke, Hampshire, England, Sept. 5, 1846. The son of a major in the Bengal Army and educated at Eton, the 15-year old boy sailed back to India in 1800, a writer in the East India Company's service. Four years later, he became political assistant to General Lake during the Mahratta war. Several increasingly important appointments followed. In 1822 he succeeded his brother in the baronetcy, and five years later obtained a seat on the supreme council. First governor of the new presidency of Agra, in 1835 he succeeded Lord Bentinck as provisional governor general of India. Resigning in 1838, he was appointed governor of Jamaica. Illness compelled his return to England in 1842, but the following year he went to Canada as governor general. A malignant disease compelled his retirement in 1845 when he was awarded a barony for distinguished service.

METCALFE, Samuel L., American physician and scientist: b. near Winchester, Va., 1798; d. 1856. In 1823 he was graduated in the medical department of Transylvania University; established a medical practice at New Albany, Ind., and visited England in 1831. Upon his return to his native country, he made a geological tour in Tennessee, North Carolina and Virginia. Later he settled in New York where he took up scientific work. He published *Narratives of Indian Warfare in the West* (1821); *A New Theory of Terrestrial Magnetism* (1833); *Caloric: Its Mechanical, Chemical and Vital Agencies in the Phenomena of Nature,* 2 vols., 1843 (2d ed., 1859).

METCHNIKOFF, Élie, Russian bacteriologist: b. Kharkov, Russia, May 15, 1845; d. Paris, France, July 15, 1916. Following his education at Kharkov, Metchnikoff studied at Giessen and Munich, and in 1870 he was appointed professor of zoology at Odessa. He held this post until 1882, when he resigned to devote himself to private researches into the anatomy of invertebrates. It was while working at lowly organized forms of life such as sponges that he first made the observations which constituted the basis of all his subsequent work. In 1888 he had attracted the notice of Louis Pasteur, the founder of the famous Pasteur Institute for the treatment of rabies, in Paris, and he was invited to become one of Pasteur's associates. In 1895 he succeeded as the director of the institute, a post which he held to the time of his death. In his study of longevity, Metchnikoff came to the belief that it should not be uncommon for persons to live to the age of 150 years. He found every indication that the human mechanism was calculated to last far longer than it actually does. His researches showed among other things that animals which had no large intestines lived to an advanced age, particularly birds, which preserve their youthful agility and spryness to the end of their long span. In the case of human beings, he found that even among those whose sufferings were terrible, there were few who wanted to be put out of their agony by death. They all wanted to live. If the normal specific longevity were attained by human beings, he believed that old and not degenerate individuals would lose the instinct for life and acquire an instinct for death and that as they had fulfilled the normal cycle of life, they would accept death with the same relieved acquiescence as they now accept sleep. On his seventieth birthday, in 1915, Professor Metchnikoff received a present of a golden book, forming a unique record of the latest scientific researches, signed by men of science of the day. Although there was much controversy in the scientific world regarding his original ideas, he was fully recognized as one of the most eminent bacteriologists. In 1908 the Nobel Prize for medical research was divided between the late Dr. Paul Ehrlich, of Berlin, and Professor Metchnikoff. The $20,000 which he thus received he devoted entirely to the furtherance of his scientific researches. Personally he was not well off, and throughout his long life sacrificed all but the plainest living necessities to the cause of science. He was the author of a number of books including *Lectures on the Comparative Pathology of Inflammation* (London 1893); *Immunity in Infective Diseases* (New York 1905); *Etude sur la nature humaine; essai de philosophie optimiste* (1903). English translations of his lectures are *The New Hygiene* (Chicago 1907); *The Nature of Man* (New York 1910). He edited, with Sacquépée and others, *Médicaments microbiens* (1909). Consult *Annales de l'Institut Pasteur* (Paris), and Slosson, E. E., *Major Prophets of Today* (Boston 1914).

METELLA, Caecilia, daughter of Metellus Creticus and wife of Crassus the Younger. Her tomb on the Appian Way about 2 kilometers from Rome is one of the best-known surviving monuments of the Augustan age. It is a circular structure of 65-foot diameter on a square base. A frieze of garlands and bucranes circles the upper part. During the 13th century the tomb was incorporated in a fortress which three centuries later Pope Sixtus V (1521–1590) tore down to bring it again into full view.

METELLI, mĕ-tĕl'ī, a Roman family of the *gens Caecilia.* Quintus Caecilius Metellus Macedonicus defeated the Achaeans, took Thebes and invaded Macedonia, and received a triumph 146 B.C. Quintus Caecilius Metellus Numidicus rendered himself illustrious by his successes against Jugurtha, the Numidian king. He took, in this expedition, the celebrated Marius (q.v.) as his lieutenant; was soon recalled to Rome, and accused of extortion and ill-management, but was acquitted of these charges. He celebrated a triumph at Rome 107 B.C. His son, Quintus Caecilius Metellus received the surname of Pius on account of the love which he displayed for his father when he besought the people to recall him from banishment in 99 B.C. In 83 B.C. he joined Sulla, with whom, three years later, he was united in the consulship. Quintus Caecilius Metellus Creticus conquered Crete, and reduced it to a Roman province in 67 B.C. Quintus Caecilius Metellus Pius Scipio, the adopted son of Metellus Pius, in 52 B.C. was colleague in the consulship with Pompey, who had married his daughter Cornelia. Hence he exerted himself to the utmost to destroy the power of Caesar and strengthen that of his son-in-law. He commanded the center of Pompey's army at the Battle of Pharsalia, and thereafter fleeing to Africa

was defeated by Caesar at Thapsus 46 B.C. He died by his own hand.

METEMPSYCHOSIS. This ancient theory has at times been confounded with reincarnation. While both imply that man lives again, the propositions present radical differences. See also TRANSMIGRATION OF THE SOUL.

METENIER, Oscar, French novelist and playwright: b. Sancoins, Cher, France, 1859; d. Saint Mandé, 1913. At the age of 24, Méténier became secretary to the police commissioner of Paris, a post he held for six years. In his novels and plays he made considerable use of the first-hand experience of underworld life gained during this period. Among his novels, which in general are quite daring, may be mentioned *La Chair* (1885); *Bohême bourgeoise* (1887); *Madame la Boule* (1889); *Barbe-Bleue* (1894). His plays include *En Famille* (1887); *La Casserole* (1889); and *Mademoiselle Fifi* (1896) adapted from de Maupassant's novel. In 1897, Méténier founded the noted Montmartre theater, Grand-Guignol, where he alternated short pieces that were either madly mirthful or gruesome. The Grand-Guignol soon became a theater specializing in sheer horror.

METEOR. The term is now restricted to cosmical bodies which enter the Earth's atmosphere from without, but until a century or two ago it included other phenomena such as halos, auroras and rainbows. In some cases this makes it uncertain whether older writers were describing true meteoric bodies or their trains, or something purely atmospheric. The science of meteorology, which covers the phenomena of the Earth's atmosphere, does not include the study of meteors, this latter being a branch of astronomy sometimes called meteoritics. As now used the term *meteor* denotes any type of body, coming from space, which makes its presence known by rapidly moving across the sky, its head generally starlike but sometimes with an apparent disk, and often leaving a luminous streak or train of light along its path. This latter usually disappears in less than a second, but in rare cases may last many minutes. For descriptive purposes we have the terms *shooting star, fireball, bolide,* and *meteorite.* The first is a popular term denoting the average meteor; a fireball is a meteor at least as brilliant as the larger planets; a bolide is an exploding fireball; a meteorite is a fireball large enough to survive its fiery atmospheric journey and fall to the ground. All the other types are destroyed at considerable heights. The word *meteor* is used both in the general sense to cover all classes, and in the restricted sense to denote what used to be called a shooting star, that is, the fainter and far more numerous members of the family, such as may be seen on any night.

It is difficult to separate the history of meteors and meteorites, so, while these latter are described in another article (see METEORITES), it is best to consider the development of ideas concerning their cosmical significance here. The fall of stones from the heavens is such an unexpected event, especially as it is usually accompanied by thunderous noises and often by smoke trains, that it must always have terrified primitive peoples, and later such events were doubtless recorded in official documents. Yet the oldest known record is that in the Book of Joshua, 10:11, where men fleeing from a battle are said to have been killed by "stones from heaven." We find that the Chinese, as early as 687 B.C., record the fall of meteorites and also describe fireballs and meteoric showers. Greek and Roman writers were less careful, some accounts being ambiguous. The oldest authentic one is of the large meteorite that fell in 467 B.C. at Aegospotami in Thrace. The oldest existing meteorite, the exact date and place of fall of which are known, is the one that fell on Nov. 16, 1492, near Ensisheim, Alsace.

In the next three centuries, a good many meteorites fell in Europe, but the reaction against superstitions of the Middle Ages led the scientists of the day to such great skepticism that they refused to face facts, in some cases. Perhaps the most notorious instance refers to meteorites: in the 18th century the learned men of the day did not *believe* stones could fall from the skies, hence they affirmed they did not. Even the great French Académie des Sciences went on record denying that meteorites had an origin outside the atmosphere, despite accounts of falls by reliable witnesses, which were ridiculed, and the splendid pioneer work of Ernst F. F. Chladni about 1794. However, on April 26, 1803, a fall at L'Aigle in France, investigated by Jean B. Biot, finally convinced even the "philosophers," and the study of meteorites, as such, began. As for the more ordinary shooting star, two German students, H. W. Brandes and J. F. Benzenberg, in 1798 carried out simultaneous observations from two stations some distance apart. Thus by the ordinary methods of triangulation, they were able to determine the approximate height at which meteors appeared and disappeared. Their average value for the points of disappearance was 98 kilometers. This proved they were far higher than clouds, but not at lunar or planetary distances. It should be mentioned that Sir Edmund Halley had calculated a fireball path in 1719, so the methods were well understood, but still scientists neglected meteors almost entirely, and we may truly say that meteoric astronomy was born on Nov. 13, 1833, when the great Leonid shower appeared over America.

The Leonids.—This shower is estimated to have furnished 200,000 meteors for a given station between midnight and dawn, numbers of them brilliant, and many leaving trains. The terror excited among the masses of the population was great, the superstitious fully expecting the end of the world was about to come. However, there were enough trained men who saw the phenomenon for several to detect that the meteors really had a radiant in the constellation Leo, that is, a point in the sky from which they seemed to shoot away as spokes from the hub of a wheel. It was quickly seen that this radiation was merely a perspective effect and that the meteors, before meeting the Earth, were really moving in parallel paths. The position of the radiant fixes the direction in space from which the meteors come. As the radiant eventually was shown to be in the same position among the stars as seen from distant stations, this proved that the meteors came from space and did not originate in the atmosphere. From then on meteors have formed a definite branch of astronomy.

Professor Denison Olmsted of Yale was the man who, at the time, made excellent observations on the Leonids and then concluded that what had occurred was due to the Earth's encounter with a swarm of particles moving around the Sun. John Locke, in America, in

1834 proved that the August meteors had a radiant in Perseus; and Lambert A. J. Quételet, of Belgium, in 1836 discovered from a study of older records that they appeared every August on about the same date. George Adolf Erman in 1839 developed a method for calculating the orbit of a meteor swarm; Sears C. Walker developed another in 1841; and it is stated that Palm H. L. Boguslawski had done so even earlier. Alexander C. Twining's work in 1862 pushed the knowledge of the Perseid orbit much further. But the truly great advances were made by Hubert A. Newton of Yale and Giovanni V. Schiaparelli of Italy. The former in 1863 proved from a search of ancient annals that we had been meeting Leonid meteors in great showers at least back to 902 A.D., though the date then was October 12. He showed that this change of date was to be expected, as our calendar is based on the tropical year, whereas the meteors would follow the sidereal year. He gave a table showing there were great showers in the following years: 902, 931, 934, 1002, 1101, 1202, 1366, 1533, 1602, 1698, 1799, 1832, and 1833. From this he deduced a period for the stream of 33.25 years, and a shower was predicted for 1866 or 1867. (Since Newton's day, examination of Arabian, Chinese, Japanese, and Korean records have added showers in: 935, 967, 1035, 1037, 1237, 1238, 1465, 1466, 1532, and 1566.) This prediction was fulfilled by an excellent shower in 1866, another good one in 1867, and a fair one in 1868. None of these, however, was anything like as wonderful as that in 1833.

Before following the Leonids further, it must be stated that Schiaparelli was able to prove to his satisfaction that most meteors met the Earth with nearly parabolic velocity, which is 42 kilometers per second. He further was the first to show that a meteor stream and a comet followed approximately the same orbit, this being done for the August Perseid meteors and Tuttle's comet, 1862 III. He embodied his researches into the first reference book on meteors (see *Bibliography*), which remained the standard work for over half a century and still should be read by all students of the subject.

Returning to the Leonids, there was general expectation of another grand shower in 1899, but, shortly before, two English astronomers, G. Johnstone Stoney and A. M. W. Downing, undertook the calculations of the perturbations which the meteors had undergone since 1866. We should pause to say that the Leonid orbit is an elongated ellipse, its aphelion point being near the orbit of Uranus. Meteors are scattered all around this orbit, which is really a cylinder several million miles in diameter, so that every November, when the Earth passes through, we meet at least a few Leonids per hour. For a certain space, however, meteors are very much more concentrated, and this is roughly a tenth of the whole circumference. Hence it takes about three years for this denser part to pass, and we go through it either three or four times in succession. During these, greater showers occur. If we go, as in 1833, through the very densest part, wonderful showers are seen; if we miss the central mass and go through outlying regions of the stream, lesser displays are afforded. The calculations of Downing and Stoney showed that Jupiter and Saturn had so perturbed the densest part of the stream, as it passed near them, that it was probable it would wholly miss the Earth in 1899. In 1898 the preliminary increase was indeed seen, and a good, if not spectacular, shower appeared, but the wretchedly poor display of both 1899 and 1900 more than vindicated the gloomy prediction. The 1901 Leonids, which had not been in position to be much influenced by the planets, furnished a good display, but nothing comparable even to that of 1868. The main stream being thus "lost," it was impossible to compute exactly what should happen for the next return. Actually, on the night of Nov. 16-17, 1931 an excellent display occurred, comparable to that of 1901, but in no other year of the period did really great numbers of Leonids appear; hence again the Earth had totally missed the densest part of the stream. As to the future, it is not possible to assert what will happen: it may be that perturbations will shift the dense part of the stream back into such a position that we will again pass through it. The next return should be somewhere between 1961 and 1967; one cannot safely be more specific. The Leonids follow the same orbit as the faint Tempel's comet, 1866 I. This should have returned in 1899 and 1932 but careful search failed to detect it.

Other Showers.—The Lyrid meteors of April were proved by Johann G. Galle in 1867 to follow the same orbit as Comet 1861 I, and the Andromedes (also called Andromedids or Bielids) and Biela's comet were proved to have the same orbit almost simultaneously by Edmund Weiss and Heinrich L. d'Arrest in 1867. Many other possible connections of meteor streams and comets were then explored, one—that of the Aquarid meteors of May and Halley's comet—being made probable though the observational data were very poor. In 1910 the final proof of this connection was given by Charles P. Olivier, based on new and adequate data. In 1916, meteors appearing in May and June, coming to a maximum on June 28, were proved independently by William F. Denning and Olivier to be connected with Pons-Winnecke's comet. In 1933 the splendid shower of Draconids, seen in Europe on October 9, was proved to follow the orbit of Giacobini-Zinner's comet. The possibility that this comet might furnish a meteor shower had been foretold some years before by Reverend Martin Davidson and by Denning. Lastly, the Taurid meteors of October, which do not give any "shower" in the popular sense, were proved to follow the orbit of Encke's comet by Fred L. Whipple. The other three annual showers, which furnish enough meteors to be worth noting here, the Quadrantids, Delta Aquarids, and Geminids, do not appear to have companion comets; the Orionids probably also are connected with Halley's comet. Some thousands of radiants of so-called minor streams have been published. At present, it is impossible to say what per cent represent real streams, though of course many do.

The Bielids furnished a grand shower on Nov. 27, 1872, a fine one in 1885, a good one in 1892, and an expiring effort in 1899. From then on few Bielids have been seen, either because the whole group has been so shifted that our Earth misses them, or because the meteors have been dispersed so that the cross section of the stream is far larger and hence the meteors more sparsely scattered. As to Biela's comet itself, it divided into two in 1845, the twins were seen in 1852 at the next return, but never since (see COMET). Both the meteors and the comet were doubtless fragments of a much larger comet, and between them represent the last stages of its dispersal

METEOR

Above: A bolide—as a meteor of exceptional brightness is often called—crosses the camera field while the great spiral in Andromeda is being photographed.

Right: Meteorite found at Cape York, Greenland, weighing 36½ tons.

Below: Chubb Crater, Quebec, from the air. The round crater is more than two miles across at the rim, and is of meteoritic origin. It was discovered in 1949.

or destruction. The cases of the two meteor streams connected respectively with Pons-Winnecke's comet and with Giacobini-Zinner's comet illustrate very vividly how our Earth may penetrate such streams on one or more occasions and then planetary perturbations shift the meteor orbits so they no longer intersect ours. For example, the perihelion distance of the first comet in 1819 was 0.77 astronomical units, in 1915 was 0.97, and in 1939 was 1.10. Meantime the orbital inclination changed from 10°.7 to 20°.1. The result was that by 1916 the comet's orbit was literally pulled far enough from the Sun to intersect ours and a fairly good display took place June 28. But the effects continued so that by the comet's next return in 1921, its orbit was wholly outside ours and a meeting with meteors moving therein impossible. As a consequence, since 1916 only outlying members of the stream have ever been seen—nothing which could be properly dignified as a "shower."

For the second comet, the period of which is 6.59 years, Denning on Oct. 10, 1926, identified a fair number of meteors as from a radiant which could be connected with the comet. Then on Oct. 9, 1933, a gorgeous shower appeared, observed in Europe, but it was over before darkness had come in America; in other words, it lasted only a few hours. Evidently in 1926 the Earth penetrated the edge of the stream, in 1933 went through what was probably its center, but not again has the shower appeared. This shower may, however, reappear brilliantly about Oct. 9, 1946. The stream must be narrow. Both of the comets move with direct motion and belong to Jupiter's family. This means they are subject to great orbital changes. These latter have given us the chance to have meteor showers. In time to come we may hope that other streams may be switched into our path.

Frequencies.—The accompanying tables will indicate the average hourly and monthly number of meteors, and the average duration, date of maximum, and richness of the principal meteor streams. They are compiled from data secured through the American Meteor Society and other sources. They refer therefore mostly to middle northern latitudes, to clear nights without moonlight, and are for persons of good eyesight.

It will be noted that the second half of the year is much richer in meteors than the first, and that the same is true for the second half of the night. The first fact is due simply to the number and richness of the meteor streams intersected by the Earth in the respective periods. The hourly duration comes as a result of the Earth revolving in 24 hours, so the zone where it is 6 A.M. is on the exact front side with respect to its orbital motion; while the zone where it is 6 P.M. is exactly in the rear. The meteoric apex is the direction in which the Earth is going at a given moment, defined by the tangent to the orbit. Our average orbital speed is 30 km/sec. (kilometers per second); that of meteors about 42 km/sec. It is easy to see then that we, in a unit of time, meet many more than overtake us. Also the relative velocities of the two groups will be $42+30:42-30$ or 72:17. When the Earth's attraction is added to the heliocentric velocities of the meteors, this ratio becomes 73:16. There is an important consequence when it is remembered that kinetic energy varies as the square of the velocity. Hence the ratio of the energy developed by a meteor coming from the apex at 6 A.M. to that of one of the same mass from the antiapex overtaking us at 6 P.M. is $73^2:16^2$ or about 20:1. Therefore we might expect more meteors to survive their passage through our atmosphere in the evening than in the morning hours, which is found to be statistically true. Also only larger bodies could survive during the morning hours.

TABLE 1

HOURLY NUMBER OF METEORS FOR WHOLE YEAR

Hour	Number of meteors per hour	Hour	Number of meteors per hour
6 P.M.	3.8	12	11.5
7	4.6	13*	13.1
8	5.6	14	14.4
9	6.8	15	15.0
10	8.2	16	14.8
11	9.8		

* 13 hours equals 1 A.M.

TABLE 2

HOURLY NUMBER OF METEORS FOR EACH MONTH

Month	Number of meteors per hour	Month	Number of meteors per hour
Jan.	7	July	10
Feb.	6	August	16
Mar.	6	September	10
Apr.	7	October	13
May	8	November	11
June	7	December	12

TABLE 3

Name	Duration in days	Date of maximum	Hourly number of all meteors on this date
Quadrantids	4	Jan. 2	28
Lyrids	4	April 21	7
Eta Aquarids	8	May 4	7
Pons-Winnecke	?	June 28	?
Delta Aquarids	3	July 28	27
Perseids	25	Aug. 11	69
Draconids	1	Oct. 9	*
Orionids	14	Oct. 19	21
Leonids	7	Nov. 16	21
Andromedes	2	Nov. 20	?
Geminids	14	Dec. 12	23

* Brilliant shower in 1933; return probable in 1946.

Orbits.—The heliocentric orbits of all meteors are conic sections with the Sun at the focus, but once the small body comes very near our Earth, the attraction of the latter becomes dominant, and so, in our atmosphere, the meteor moves in a hyperbola with the Earth's center as focus. The visible path being described usually in a second or less, and its length being only a few score miles, for the average meteor it is practically a straight line. By using observations from two or more stations, made simultaneously on the same meteor, it is possible to compute the height at which it appeared and that at which it disappeared and the path length. If an accurate estimate of its duration is made, the velocity, and, by well-known methods, its orbit in space can be computed. Even when, as is usual, the velocity is poorly determined, by assuming parabolic heliocentric velocity we derive an orbit which is nearly correct in several of the elements, especially the inclination and the perihelion distance.

The necessary observations for determining a

meteor's path have, so far, mostly been made visually. During the past half century photography has begun to play a part, but even yet only the brighter meteors can be photographed. Visual observations consist in plotting the apparent path, as seen from each station, upon a star map. Knowing how far the stations are apart and their latitudes and longitudes, the base line can be established. The ends of the apparent path being measured with respect to the stars give the right ascensions and declinations of these points. Knowing the time, the altitudes and azimuths can then be computed. We now have, in principle, the case in trigonometry for solving a triangle when the base and adjacent angles are known. It is impossible to state how many meteors to date have had their height computed, but one would be safe in estimating the number to be several thousand—quite enough to give good average heights both for certain magnitude classes and special showers. Results based upon photographs are very much more accurate than visual, but as yet are few in number. This is because faint meteors do not impress themselves upon the plates and also the faster their angular velocity, the more difficult it becomes to photograph them. Short-focus lenses of large field of view and considerable aperture are best. With small fields of view, the chances for catching meteors decrease rapidly. At observatories where there are great collections of plates, notably Harvard and Sonneberg, Germany, statistical studies have been made. At Harvard, Willard D. Fisher, in 1927, examined 71,454 plates and found 213 trails. A later search at Harvard, covering 8,077 plates taken with two instruments in 1930–1935 inclusive, netted 59 meteors; 159 more meteor trails were found on other series there for these same six years. Cuno Hoffmeister reports that at Sonneberg (about 1937) on 10,729 plates 51 trails were detected.

By rotating a sector at high speed in front of a given lens, if a meteor is photographed, the path comes out as a line with a series of breaks thereon. If a photograph at another station is available, then the heights and length of path can be computed and, knowing the timing of the breaks, not only the meteor's average velocity can be found, but the velocity in each part of its path. Pioneer work along this line was done by William L. Elkin at Yale from 1891 to 1910, and more recent work at Harvard by F. L. Whipple. Interesting and important results, including proof of the slowing up of a meteor as it penetrates lower, have come from these programs, but observational and technical difficulties have not yet permitted results on any large scale.

Spectra.—When it comes to meteor spectra, attempts made in the latter part of the 19th century with small visual spectroscopes need scarcely be mentioned in view of the relatively greater accuracy of photographs taken with objective prisms. The work of one man, Peter M. Millman, is so outstanding that it alone need be mentioned. He has, however, enlisted the aid of many observers, so that the actual plates come from various sources. In 44 spectra discussed before 1941, he finds two groups which he calls Y and Z. In the Y group of 33 spectra the two strong H and K lines of ionized calcium appear; these are absent in the 11 in Z group. Also 25 of Y are meteors belonging to the four most prolific annual showers, while 10 of Z are certainly sporadic. Iron is found in 37 spectra. Besides Fe, in order of number of cases are: Ca^+, Ca, Mn, Mg, Cr, Mg^+, Si^+, Si, Ni, Al, and Na. This list of elements so far identified may be compared with those found in meteorites. It should be noted that all objective prism spectra are of very low dispersion and only prominent lines can be detected. As sporadic meteors form all of class Z, with one doubtful exception, it might well lead to belief in a considerable difference in structure between sporadic and the shower meteors, which latter seem to be debris of comets' nuclei. The term "sporadic meteor," as used here and elsewhere in this article, simply signifies that the meteor does not belong to one of the dozen or so best-known annual streams, or those known to be connected with some comet.

Mass.—The average meteor seems to be an extremely small body. To determine its size or mass, we remember that the equation for kinetic energy is $E = \frac{1}{2} m v^2$, where m is the mass and v the velocity of the moving body. Further it can be shown that no body can strike the Earth with a smaller v than 11 km/sec., and it is nothing unusual for this figure to be as large as 70, 80, or even greater. It is then clear that v^2, expressed in the usual units, is a great quantity, and E may still be large, even when m is very small. By knowing how bright a meteor is, its path length, its duration, and how far it is from the observer, then a good estimate of the amount of light-energy it emits can be made. If all its E went into light, then our problem would be easier, but much goes into heat and probably also into other forms of energy. So assumptions are necessary. Accepting what seem the more probable, it is surprising to find that a meteor as bright as Jupiter may weigh only 4 grams, one as bright as Polaris 40 milligrams, and one just visible to the eye 1 milligram only. Fletcher G. Watson computes that daily the mass of meteors which strike us amounts to 1,000 kilograms, the meteors ranging from −10 to +30 magnitude. The latter are the smallest bodies which could move under gravitation and not be seriously affected by radiation pressure. He computes the true number of meteors, including those of +6 magnitude, or all visible to the eye, to be about 185,000,000 daily, while from +7 to +10 magnitude inclusive, or those visible in a small telescope, there would be 7 billion. These estimates are larger than most earlier ones, but are based upon more modern data.

Heights.—Meteors are mostly visible in that stratum of our atmosphere extending from 130 to 70 km. from the ground. Exceptional ones may begin higher and penetrate lower. It is obvious then that the average meteor one observes will be 70 to 200 kilometers distant. How can such minute bodies be seen so far? The answer is that they *are not*: it is the results of the energy they develop which we see. The small, solid body rushing through even the tenuous upper atmosphere continually strikes air molecules, heating them, and they in turn heat the surface. Those in front of the solid nucleus are greatly compressed so it is surrounded by an envelope of incandescent gas, much larger than the body itself. It must indeed be remembered that a lot of heating takes place and perhaps even some loss of mass occurs, before the body becomes visible. As it rushes into denser air, the surface is continually sloughed off, and the average meteor will be wholly consumed above the 70-km. level. However, the resulting debris,

gas and dust, add to the Earth's mass. The first stays in the atmosphere, the latter eventually settles. Traces can be found in polar snows and even deep-sea dredgings.

The geocentric velocity of a meteor seems to determine the height at which it first appears, the greater the velocity, the greater the beginning height. The Leonids, 70 km/sec., Perseids 56 km/sec., are cases in point. Results for 1932–1934 from work by the American Meteor Society (A.M.S.) give for Leonids $H_1 = 124$ km. (220 meteors) and $H_2 = 92$ km. (232 meteors). Results by Weiss on 49 Perseids give $H_1 = 115$ km. and $H_2 = 88$ km., respectively. A.M.S. results for sporadic meteors, observed on the same nights the Leonids appeared in 1932–34, are $H_1 = 106$ km. (177 meteors), and $H_2 = 83$ km. (183 meteors). V. V. Fedynski for the period 1930–1933, using a new method, derived for 62 Leonids $H_1 = 128$ km., $H_2 = 92$ km. These agree excellently with the A.M.S. values as do those derived from the Yale photographic campaign by Elkin. Ernst Öpik, in his results of the Harvard-Cornell Meteor Expedition of 1931–1932, derives for what he calls "shower meteors" $H_1 = 103$ km., $H_2 = 85$ km., while for all meteors $H_1 = 95$ km., $H_2 = 82$ km. He preferred to use harmonic means which appear in all cases to make H_1 and H_2 smaller than arithmetic means. Large meteors or fireballs penetrate often to 30 km.

Trains.—Most meteors leave an evanescent streak along their path which quickly disappears. The brighter ones often develop trains which last from one to many seconds. But exceptional meteors and fireballs occasionally leave trains which remain from a few minutes to even a couple of hours. Charles C. Trowbridge was the first to undertake serious researches upon long-enduring trains. His work appeared from 1906 to 1911. In this he proved that the stratum in which night trains appeared was that from 72 to 105 km., mean value 87 km. As for the cause of luminosity, he assigned phosphorescense of the atmospheric gases following preceding ionization, and showed that duration and brightness of the trains agreed well with laboratory experiments. He showed that trains were cylindrical and that they rapidly expanded; also that their drift furnished the means of finding the direction of winds in the stratum where they occur. Velocities for drift up to 300 km/hr. were found, and it was further proved that thin layers, even when adjacent, had winds blowing in different directions and with different velocities. This means that the original train not only expands its diameter, but takes many forms, often fantastic in shape. In 1921, S. Kahlke, bringing the researches upon drifts partly up to date, showed that, for night trains over 80 km., a west wind was predominant over both America and Europe, but with a strong southern component for the former, a weak northern component for the latter. This he explains on the basis of the European observations being made in higher latitudes, on an average. For day trains, between 25 and 80 km. height, for Europe he found an east wind, but there were too few cases for much certainty.

In 1941, Olivier published a much more extensive research on trains, having not only two more decades of results to handle, but finding in older literature numerous cases overlooked by the two investigators mentioned. Among his results are that for night trains the averages are: $H_1 = 102$ km., $H_2 = 74$ km., for day trains: $H_1 = 57$ km., $H_2 = 30$ km., while the average velocities are respectively 175 km/hr. and 133 km/hr. This clearly indicates higher wind velocities at greater heights, on the average. It was also proved, in a few cases, that the winds were not merely horizontal but had strong vertical components. As sounding balloons have not yet been able to explore our atmosphere above some 37 km., it is obvious that train drifts furnish our best method for getting wind velocities in the stratum where they occur, and hence are of great value to meteorology. Excellent systematic work has been done since 1920 in this, as well as all other branches of meteoric research, by Russian astronomers.

The trains left by bodies visible in daylight average, as said, much lower. These indeed must largely consist of dust and smoke, which show up by reflected sunlight. The night trains, on the contrary, cannot be so illuminated, and hence their light must be inherent. Twilight trains may be composite. The great fireball of March 24, 1933, over Oklahoma and New Mexico left a long-enduring train from 100 km. at the beginning to 25 km. height at its end. It also dropped stone meteorites. Explanation of how such a train, particularly the lower part, remained visible is more difficult. The upper part was in sunlight but at an altitude at which day trains do not usually extend. The Sun had not risen for the lower, western end. Excellent photographs were secured of this train, as well as of a few others before or since.

Under the head of telescopic meteors may be included all which are fainter than +6 magnitude. Every observer at intervals must see a meteor shoot across the field of his telescope, but the number of serious studies of the little bodies have been few. With regard to shower meteors, observations have been made at the maxima of the Perseids and Bielids particularly. One interesting result by Adelbert Safarik in 1885 for the great shower of that year was that, in his telescope, he did not see many meteors fainter than +9 magnitude, and inferred that few smaller particles existed in the Bielid stream. Fletcher G. Watson in 1936 concluded that "from a preliminary study of strong meteor showers we are led to expect relatively few telescopic shower members." Öpik concluded that most sporadic telescopic meteors had hyperbolic velocities and hence come from space beyond the solar system. J. Hoppe in 1935 considered that he was able to prove that the daily variation extended to telescopic meteors. Some observers have been disposed to think such meteors are very much higher than the average naked-eye object, but this cannot be considered as proved, or indeed very likely.

Meteoric observations are particularly suited to amateurs, not indeed that they are easy to make, if plotting is part of the program, but because professional astronomers can spend but little time away from their telescopes. Hence much of the best work has been done by amateurs who were able to devote enough time to secure results over long periods. Outstanding among such men was William F. Denning (1848–1931) whose work, over many decades, brought him deserved reputation. From about 1867 to 1872 there was an efficient association in Italy. The Meteor Section of the British Astronomical Association has been active for many decades

doing most excellent work. The American Meteor Society, founded in 1911, had up to 1946 made about 400,000 observations, perhaps one third of the meteors plotted and fully recorded, the rest mostly planned comets. In the USSR since 1920 there has been the greatest activity among both professionals and amateurs, and excellent work of every type was done on meteors. In this connection I. S. Astapowitsch and V. V. Fedynski have been leaders. There was a flourishing society in Czechoslovakia prior to World War II. There is also a society in Japan doing good work. Individuals and, at intervals, groups in many European and a few other countries have functioned effectively.

Despite all that has been done, there is a vast field for future endeavor. This can be along two lines: devising new methods or instruments, or the attempt to use those we have in a more effective manner. Nearly all previous work has been done in Europe and North America; the Southern Hemisphere has been relatively neglected. Statistical studies on such bodies as meteors should be made from many places on the Earth, widely distributed, if we would have full information. Then there are problems which can best be attacked at fixed observatories. Primarily here would be wider application of photography to meteors, both to secure more accurate paths and heights, but most of all to settle the vexing question of their velocities. So far, due to obvious selection, the velocities secured must have been for slower moving bodies, and for the brighter ones. We need accurate velocities for the more average meteors. Not until these can be derived instrumentally can the question of where they originated be settled. If their heliocentric velocity is over 42 km/sec., then they are from outer space; if less, then in general they originated in the solar system. There has been great controversy on this point, since, unfortunately, visual observations as to durations are perforce inaccurate and hence the derived velocities must be also. Cuno Hoffmeister's important work, which appeared in 1924 and later, indicated that most meteors, omitting those belonging to the principal annual showers, had a strongly hyperbolic velocity. This was based on his interpretation of the daily variation. Also the majority of the 611 fireballs contained in the Von Niessl-Hoffmeister *Catalogue* (1925) give hyperbolic velocities. This latter result was strongly criticized by W. D. Fisher, and later by Charles C. Wylie, who believed that errors in the data are responsible for the high velocities found. Yet the results of the Harvard-Cornell Expedition, both by the rocking-mirror method, which is a partly instrumental one, and by another approach to the problem, according to Öpik confirm the high velocities of sporadic meteors. But Watson (see *Bibliography*) indicates clearly that, as to the fireballs, he believes the large velocities erroneous. Whipple's work on the Taurid meteors, which Hoffmeister had worked out as an interstellar stream with high velocity, showed them to be connected with Encke's comet and really of low velocity. With all this disagreement among the best authorities, it is clear that no more important problem awaits solution than that of meteor velocities. On the answer will depend how meteors must fit into the general evolutionary picture, and, as meteorites are the only extraterrestrial bodies we can analyze, they must furnish an important key to evolution

The importance of meteor trains for studies of the upper atmosphere has already been explained. But determination of accurate heights and path lengths also give information as to the temperature, pressure, and possible composition of the stratosphere. Nearly all of this work has been and will have to remain visual. We need more and better data. Studies of meteor rates help to determine the quantity of matter in space, and the density of meteor streams. In turn we are led to a better understanding of the composition and course of dissolution of comets. Up to 1946 no one had succeeded in getting the spectrum, by photography, of a meteor train. When this is accomplished we will have direct information on the composition of our atmosphere at the heights in question. We need convincing parallax determinations of telescopic meteors to see whether they are faint because small though at average heights or are of average size at great heights. This last, like many other important problems, could be undertaken by amateurs with the proper training and instruments. All the societies mentioned welcome persons interested in the subject, and generally furnish them with full instructions and aid in starting their work.

Origin.—At present, all theories of evolution in the astronomical sense are in a state of flux, or, it would be better to state that no one has general acceptance among scientists. Such being the case, it is impossible to be certain as to where or how meteors originated. We may say that shower meteors are debris of comet nuclei, but no one has any clear idea of how a comet came into being. If, as the writer believes with many others, most sporadic meteors come from space, cometary origin is scarcely credible. Are these tiny bodies indeed the building block of evolution or its debris? If anyone could explain how such small bodies could form out in space from molecules or atoms of gas, the former would be a very comfortable hypothesis. But no one ever has, so far as the writer knows, given an even partially adequate explanation of such formation. We are then driven back to the debris hypothesis, and at present it seems the more logical of the two. In this, meteors are debris of evolutionary processes by which large bodies are born into the embryonic stage. From here on some attain full growth, others are destroyed before, or perhaps after, reaching it. For every large fragment, say of asteroid size, there would be innumerable small ones, down to the dimensions of dust. These tiny particles, scattered in vast numbers through space, give us our meteors; those a little larger, and hence far less numerous, our meteorites. In historic times we have not met a body of the next order of size, that of a small asteroid, but our Earth is itself of moderate area, space is vast, and human history short. There is not the least reason to doubt such bodies do exist, and given time enough we shall find it out in a most unpleasant manner when one finally collides with us. We should hasten to add that some meteorites, the orbits of which have been calculated, originated in the solar system: we know of asteroids of short period which come inside our orbit. It being the writer's opinion that the same processes, which formed them here, formed similar bodies in distant systems, the only question we need ask further is how the sporadic debris escaped into space. The answer would be rather

technical but should follow the type of explanation as to how a comet can attain hyperbolic velocity, which we occasionally find has occurred. Studies of space absorption and the masses of spiral nebulae also lead independently to belief that innumerable particles of meteoric size and larger exist beyond the confines of the solar system. So while a complete account of *why* they are there cannot as yet be given with any certainty, we have many good reasons for believing they *are* there.

CHARLES P. OLIVER,
Director, Flower and Cook Astronomical Observatories, University of Pennsylvania.

METEORITE, a solid mass which enters the Earth's atmosphere from without and survives its fiery passage to fall upon the Earth's surface. Previous to this encounter, a meteorite travels in an orbit which is a conic section, our Sun being at one focus. Closely approaching the Earth, the latter's attraction adds to its heliocentric velocity, hence it can be proved that the minimum velocity with which an outside body can strike us is 11 km/sec. (kilometers per second), while the maximum has reached perhaps as high as eight times this value. Just before collision, the temperature of the meteoric body would be that of a small airless planet at one astronomical unit from the Sun, or about 4°C., not near absolute zero, as is sometimes erroneously stated. Entering our atmosphere, even in the tenuous upper regions, the body would be heated by collision with air molecules, the friction or heating becoming greater as it penetrated lower. And meantime a large gas cap would be formed in front, the gases therein being tremendously compressed, and carried along with it. The surface becomes greatly heated, and in fact melts and sloughs off, and eventually the resistance, due to increased air density, not only slows but virtually stops the body at a height of some 20 to 30 km. Having lost much or all of its cosmical velocity, from this height it drops down under the Earth's attraction. This explains why any meteorite, actually seen to fall, never penetrates deeply into the ground. The greatest penetrations known are only a few meters, while small meteorites are found lying on the surface; one fell upon lake ice a few inches thick without breaking it.

As the time of passage through the air is measured in seconds, heat has no chance to penetrate from the surface into the interior by conduction. The heating and melting are therefore superficial. While meteorites are doubtless warm when they first fall, accounts of their being extremely hot, or setting fire to vegetation, seem certainly exaggerated. If they come at night, they are usually visible from a height of 120 km. or more, to 20 or 30 km.; below this, it is doubtful if many are seen. Some attain at their brightest the brilliancy of the full Moon, or even more when they burst or flare up. Such bursting is doubtless due to tremendous air pressure on their front surfaces, plus sudden surface expansions. A meteorite acts like a typical fireball while visible in its atmospheric path. The rapid passage through the air, which is violently disturbed, often produces sounds like rolling thunder, artillery fire, or even explosions. These are sometimes violent enough to shake houses. If the body comes during daylight, it is usually detected at lower heights and, by contrast, against the sunlit sky will not be so brilliant. It is accompanied often by clouds of smoke and dust, which debris at times remains visible for long intervals after the body itself has fallen. Some meteorites "explode" into many fragments; others fall in a single mass or at least only one is found. In the first case, fragments may be dispersed over an area of several square miles. When a meteorite is found, its surface to the depth of about a millimeter has a black, fused crust. This is, of course, due to the last melted material which was not brushed off by the air during its passage. Irons usually have pitted surfaces, the smaller depressions looking not unlike deep thumbmarks. When a meteorite has lain on or in the ground for a long time, larger cavities are formed by the removal of the less refractory materials through weathering. Stone meteorites, unless promptly found, are likely to be permanently lost. This is because they look not unlike ordinary rocks and they disintegrate rather rapidly. Irons, on the contrary, may survive for centuries and still be recognizable. Curiously, however, only one meteorite has been found embedded in ancient strata. This was in the Pliocene gravels of the Klondike. The history of meteorites is briefly touched on in the article METEOR, as the subjects overlap. As additional information, there is reason to believe that the (original) image of Diana at Ephesus, which "fell down from Jupiter," must have been a meteorite (see STONE WORSHIP). Several Greek or Roman writers describe the fall of other stones from heaven, which were thereafter held in veneration. The Chinese record a fall in 644 B.C. The sacred black stone built into the Kaaba (q.v.) at Mecca, which may still be seen, is believed to be a meteorite. Despite the skepticism of 18th century scientists, a few meteorites which fell before 1800 were preserved.

The German philosopher Ernst F. F. Chladni in 1794 seems to have been the first eminent man to give scientific reasons for believing certain metallic masses could not have formed on the Earth. The researches of Jean B. Biot in 1803 first convinced his colleagues that witnesses' accounts of the L'Aigle, France, fall were true and that the stones came from space.

In 1953, we have specimens of over 1,400 falls, about one fifth of which were actually seen to occur. (The one fifth is based upon data from the United States only.) Most of these objects fortunately are in large museums: the National Museum in Washington, D.C., the Field Museum in Chicago, Ill., and the British Museum have outstanding collections; and before World War II the Natural History Museum of Vienna had a noteworthy collection. There is a fine exhibit at the Vatican Museum, and also in other places, though not so large as those mentioned. Small collections by private citizens should be discouraged, since too often, on the death of the owner, they are dispersed or lost.

Meteorites are roughly called either irons or stones, but the more accurate classification is as follows: (1) irons or siderites, consisting mostly of nickeliferous iron; (2) stony-irons or siderolites, in which iron and stony matter are both mixed in large amounts; (3) stones or aerolites, consisting mostly of stony matter. There are two subdivisions of this last: (a) stones poor in

iron, generally without round chondrules, (b) chondrites, with some bronzite, olivine, and nickel-iron, and many rounded chondrules. It is obvious that while most meteorites fall clearly into one of the three main groups, there must be some borderline cases. Up to August 1943, the Society for Research on Meteorites listed 1,366 falls or finds classified as follows: in Class 1, 491 cases; Class 2, 61 cases; and in Class 3, 814 cases.

Among the elements which have been detected in meteorites by either chemical or spectroscopic analysis, no new one has been found. This indicates that the same elements exist everywhere in space. Yet combinations of minerals are found which do not occur on our Earth. This latter is one of the proofs that these bodies were formed elsewhere and came to us fully developed. In 1945, consulting five different authorities, it was found that 55 of the 96 chemical elements have been detected in meteorites. It is interesting to note that of the elements with atomic numbers 1 to 33 inclusive, 30 have been detected; from numbers 34 to 56 inclusive, 14 elements have been found; but from numbers 57 to 96 only 11 are known.

Meteorites, even of the same class, differ considerably in their composition; hence individual analyses deviate much from the average. In general, however, speaking of stone meteorites in comparison to the Earth's crust, we find over five times the percentage of iron but only about three fourths that of oxygen and silicon. The other well-known elements common to both are in quite different percentages. We would, therefore, not expect to find in meteorites the same minerals or compounds which are familiar to us here on the Earth. The stones, in general, belong to a very basic class of rocks, low in silicic acid but high in iron and magnesium. Undoubtedly they have the characteristics of igneous, not sedimentary, rocks. The stones are very complex in structure and much fragmented. Many show intrusions of other minerals which must have occurred after their original consolidation. The irons consist essentially of alloys of iron, nickel and cobalt, with which are commonly associated the phosphide schreibersite and the sulphide troilite. It is this type in which have been found small quantities of the rarer elements, including gold, iridium, and platinum. In iron meteorites, which usually have from 7 to 15 per cent of nickel, a surface, polished and then treated with acid, shows characteristic patterns of intersecting bands, known as Widmanstätten figures. They are due to the inequality of the acid's action upon thick or thin plates of the various constituents, which are largely kamacite and taenite. The latter is richer in nickel than the former, and the bands narrower. The bands are indeed edges of plates arranged parallel to the faces of an octahedron, the form crystallization had taken. Such meteorites must have formed under conditions of high temperature and great pressure. Indeed they must once have been in a liquid state and cooled slowly. Meteorites did not form in the presence of free oxygen. Reports of the finding of bacteria in meteorites are not thought to be correct.

Important Meteorites.—The largest meteorite discovered, if we omit the highly controversial Adrar or Chinguetti mass, is that still lying near Grootfontein, Southwest Africa, called the Hoba West meteorite, the present weight of which is estimated at 60 metric tons.[1] Allowing for the iron-shale around the meteorite would add 20 tons to the present weight. It is uncertain just when this was discovered (1920?), but in any case it had been lying there certainly for centuries. The next largest meteorite is the Ahnighito, or The Tent, brought from Greenland by Admiral Robert E. Peary in 1897, weight 33.1 tons. This, with two others from the same region but much smaller, and the Willamette from Oregon, weight 14.2 tons, are all irons and are in the Hayden Planetarium, New York City. Mexico possesses four very large irons: Bacubirito, 24½ tons; Chupaderos I, 14.1 tons; Morito, 10.1 tons; and Chupaderos II, 6.8 tons. The other very large iron is Mbosi, 12 tons, in Tanganyika Territory, Africa. Incidentally, the largest specimen found at Meteor Crater, Arizona, is about half a ton. No record survives as to the fall of any mentioned above.

Turning to stone meteorites, we find a different result. This is in part because irons will last for thousands of years, if large, and still be recognizable, while stones will decay. The largest single stony mass fell Feb. 17, 1930, at Paragould, Ark. Its weight is 338 kilograms (745 pounds). Three other pieces from this fall weighed 73 kilograms more. The next, Knyahinya, Czechoslovakia, weighed 293 kilograms. Two very large ones—Long Island, Kans., total weight of fragments 564 kilograms, and Bjurböle, Finland, 330 kilograms, were broken into fragments either in the atmosphere or on impact. All these were seen to fall. The fall at Pultusk, Poland, Jan. 30, 1868, seems to break all records. About 100,000 fragments were picked up, the largest 9 kilograms; the smallest perhaps 1 gram. Of these, about 200-kilogram weight has been preserved. The Estherville, Iowa, fall of May 10, 1879, also furnished thousands of fragments, total 338 kilograms. At Holbrook, Ariz., July 19, 1912, some 15,000 stones fell, total 219 kilograms. At present, many more falls are composed of stony than of iron meteorites, the proportion being about 9 to 1. Also most of those irons *seen* to fall have consisted of a single mass: the stony falls may be from one to many thousand. That we have so many irons in our collection is because, as pointed out in the case of large masses, irons survive weathering longer and attract more attention.

In modern times, meteorites have struck houses and fallen very close to people, but we have no authentic accounts—except that in Joshua—of people being killed. Taking the United States, for example, the distribution of meteorites is most surprising. For instance, up to 1941, 28 had been found in North Carolina, and only 2 in Illinois—a more populous state of about the same area and with no mountains. The southern Appalachian region seems much favored, as are Texas, New Mexico, and Arizona; but the three very populous states, Massachusetts, New York, and Pennsylvania, had only 0, 7, and 6 respectively. Colorado had 39 and Kansas 50, but this is due largely to the work of Harvey H. Nininger, who has explored that territory. Were thorough surveys made in other states, considerable numbers might be discovered, but no good explanation has been given for the curious distribution so far shown. Obviously, regions of small rainfall are those most favorable for me-

[1] The metric ton will be used in this article. It equals 2,205 pounds or 1,000 kilograms.

teorite survival and eventual discovery. It is clear that but few of the fallen masses are in any case recovered. The Earth is about three fourths covered by water; all meteorites that fall on the water areas are lost. Besides, there are vast regions near the poles where no one lives; great areas of jungle and much other uninhabited country. Even when small masses fall in thickly settled areas, unless the exact place of fall is known and at once examined, the chances for finding the meteorite are poor. It would be a very liberal estimate to say that one out of every hundred is recovered.

Meteor Craters.—By far the most important effects produced upon the Earth's surface by the fall of outside bodies are the so-called meteor craters. Several have been discovered and doubtless there are many others. They were probably caused by the impact of not one mass but of a rather compact group of meteorites, perhaps we could say the nucleus of a small comet, at least in some cases. The first to attract attention is Meteor Crater in Arizona. Around this, thousands of meteorites, weighing in the aggregate 10 to 20 tons, have been picked up. At first believed to be a peculiar effect of vulcanism, its true character was definitely proved by Daniel M. Barringer in 1909 to be due to impact. This crater is 4,000 feet in diameter and 570 feet deep, with a rim that is from 130 to 160 feet above the surrounding plain. Its bottom is filled to an extra depth of 600 feet by pulverized rock. The otherwise horizontal strata which form its walls are arched in the southwest quadrant. Geophysical surveys also indicate there is magnetic material buried there. Despite this, scientists are now divided into two schools of opinion. One, trusting to the surveys and borings, believes that large metallic masses survive, buried under the southwest quadrant; the other, basing its conclusions on computations of what would happen when a mass great enough to make the crater struck, believes it was vaporized on contact. The writer is in the first group, being more inclined to trust to actual observations than theory, especially as men have never witnessed such a catastrophe at close range, or, if so, lived to report what really took place.

There is a group of craters, 13 in number, at Henbury, Australia, the largest being 660 by 360 feet; the smallest, only 30 feet. Iron meteorites have actually been excavated from some of the smaller craters of this group.

The Odessa Crater in Texas is 530 feet in diameter and has a depth of 18 feet with a very low rim. Numerous small meteorite fragments have been found around that.

Besides these we know of other craters. The most famous of the seven are the Siberian Craters, formed on June 30, 1908. The former were caused by a group of meteorites which crossed Siberia from south to north, falling at a spot in position longitude 101° 57′ E., latitude 60° 55′ N. It was not until 1927 that an expedition under L. A. Kulik found the place, and therefore it was long after the event before observers were interviewed and data collected. There were numerous small craters, and around the area the forests had been seared and flattened, the trees lying with their tops away from the center, over an area of from 30- to 50-kilometer radius. No meteorites are known to have been recovered. The principal damage had been done by the blast of superheated air, coming from that carried along by the solid fragments, where air and fragments struck the ground. The fall occurred in an uninhabited area. Had it struck a great city, the latter would have been destroyed. More recently, several large craters, all believed to be meteoric in origin, have been located. Wolf Crater lies in northwestern Australia. It is about one half mile in diameter and 100 feet deep. Chubb Crater in northern Quebec is the largest known. It is 2½ miles in diameter and part of its rim, composed of fragmented granite, is 550 feet high. The interior is filled by a lake whose level exceeds considerably that of others nearby. In the East Pamir highlands of the U.S.S.R. two smaller companion craters exist. The larger is 260 feet in diameter and 50 feet deep; the smaller 52 feet in diameter. In this case there is a legend about a "fiery star" falling there two or three centuries ago. Lastly, on Feb. 12, 1947, a swarm of iron meteorites fell in southeastern Siberia. At least 106 craters, the largest 90 feet in diameter, were formed. A considerable weight of iron meteorites was recovered and it is estimated that perhaps 1,000 tons formed the original mass. Several other "craters" have been suspected as being impact in origin but are not considered as certain by scientists.

Origin.—There seem but two possible types of hypotheses as to the formation of meteorites: they come from small masses of gas and dust which somehow condense out in space, or they are debris of larger bodies which have disintegrated. While certain eminent men have leaned to the former theory no one has been able to show how the extremely complex meteoric structure could evolve under such conditions. For it is obvious that the structure of meteorites, shown when they are examined under the microscope, must be the result of very complicated actions. Unless this point can be explained, it would seem that we are driven to the second method of formation. Here we are at liberty to think of an exploded planet, asteroid, or possibly a star, and disintegrated nuclei of comets. There seem no grounds for believing that meteorites could have been fragments of our Earth.

To determine the age of meteorites would aid in settling their origin. Helium and lead are products of radioactive elements. As the rate of radioactive decay is known, for instance the total amount of helium accumulated in any period, divided by the actual rate of production of helium in the meteorite, gives the age of the latter. The method is more applicable to irons than stones, it being assumed gases can escape more readily from the latter and not at all from the former, once solidification of the minerals has taken place. Work by Fritz Paneth, William D. Urry and W. Koeck on 23 irons indicated their age as being from 10^8 years for the "youngest" to 2.8×10^9 years for the "oldest." If these ages are correct, none seems older than the Earth. Measurements on the Pultusk stones gave 5×10^8 years, but this estimate is without doubt much too low, as the stones are at least semiporous. In comment, the results depend upon the *assumption* there has been no leakage. In millions of years, meteorites moving in what is a practically perfect vacuum, and heated on each approach to our Sun (or any other star), *may* lose some of their gas. If so, their ages would be greater than indicated above.

Some at least have such low velocities that

we know they belong to the solar system and originated therein. Some of their orbits resemble those of short period comets. For others, observations (which are always very uncertain as to duration) give hyperbolic orbits. If these orbits are *truly* hyperbolic, then these meteorites came from other parts of space. They could not have evolved in the solar system. Even so, this only tells *where* not *how* they came into being. The two hypotheses on their origin that now are available have been mentioned. As with meteors, accurate velocities will settle whether they were permanent members of our solar system or not.

METEOROLOGY, the branch of physics dealing with the atmosphere and its phenomena. The term *weather* refers to the state of the atmosphere with respect to temperature, pressure, humidity, wind, cloudiness, and precipitation at any instant or over a period of time. A distinction is drawn between weather and climate (see also CLIMATE) in that the latter is the integral or totality of weather at a place over a long period of years.

History.—Man's interest in the atmosphere has existed since primitive times because his life has always been greatly affected by the weather. Of necessity, he began to observe the weather so that he might be able to protect himself from its vagaries. He soon learned that certain atmospheric phenomena were connected with certain kinds of ensuing weather. Thus, the solar halo was early recognized as a precursor of rain, and twilight colors were given a significance.

The early Greeks applied their philosophy to weather phenomena. Aristotle's *Meteorologica*, which today seems so naïve, nevertheless remained a standard treatise on meteorology for 2,000 years (c.350 B.C.–1650 A.D.). It was not until the 16th and 17th centuries following the stagnation of the Middle Ages, that meteorology along with other sciences began to progress. The invention of the thermometer (c.1593) by Galileo and the barometer in 1643 by Evangelista Torricelli brought the beginning of the period of exact weather observations. Observations were then begun in Italy and spread slowly through Europe and to America in the next century. From observations at only a few points Benjamin Franklin recognized that individual storms move from place to place over the Earth's surface. About 1820 the German physicist and astronomer Heinrich Wilhelm Brandes (1777–1834) collected observations in Europe, all of which had been made at the same time some 37 years earlier at various places, and plotted them on a map. This was the first synoptic weather map. About a year later, William C. Redfield (1789–1857) prepared synoptic maps in the United States based on more recent data. Shortly after the establishment of the first commercial telegraph line in 1848, Joseph Henry and James Pollard Espy organized a regular telegraphic weather service in the United States. With observations collected from many places by telegraph, synoptic maps showing the weather existing only a few hours earlier could be constructed. Soon thereafter, weather services were organized in France, Holland, and England. In 1870 the United States Weather Bureau was established (see WEATHER BUREAU). In more recent years, teletype, radio, and facsimile have made possible the rapid collection and exchange of meteorological reports from vast ocean regions and remote land areas over most of the Earth. In addition, the speedy dissemination of weather maps and forecasts has been facilitated.

The nature of systems observed on weather maps has been the subject of much study since the middle of the 19th century. In 1841 Espy was among the first to point out the importance of expansion and cooling of rising air in producing clouds and thunderstorms. Heinrich Wilhelm Dove in 1857 published *Das Gesetz der Stürme* (*The Law of Storms*), in which he attributed the development of large-scale storms (cyclones or low pressure areas of temperate latitudes) to the interaction between tropical and polar air currents. In 1860 the Dutch meteorologist, Christoph H. D. Buys Ballot formulated his famous law (Buys Ballot's law) on the relation between pressure and wind. During the period of World War I (1914–1918), Vilhelm Bjerknes and several collaborators in Norway developed the principles of air masses and fronts. They theorized that large-scale storms developed from large waves along a boundary or front between air masses of differing characteristics. During the 1920's and 1930's these new air mass and frontal concepts revolutionized the whole theory and practice of temperate zone weather analysis and forecasting. As observations of the upper air became fairly numerous in the 1930's and 1940's, hydrodynamic wave theory was applied to the wavelike upper-level circulations. Much of this work has been done in the United States by many workers, among whom the most notable have been Jakob Bjerknes and Carl-Gustaf Rossby.

Definitions of the Meteorological Elements.—*Pressure.*—Pressure refers to the weight of a column of the atmosphere above a given place of observation. It is hard to realize in the quiet of a room that air has weight or can exert any pressure. But actually the air in a room 10 by 10 by 10 feet weighs about 75 pounds. Since air has weight, the whole atmosphere presses down upon the Earth's surface beneath it. The average force is about 14.7 pounds per square inch at sea level. Pressure has been expressed most frequently as the height of a column of mercury of equivalent weight (as read from the mercurial barometer). It is now customary to express pressure in millibars, which are units of the metric system. Thus, the average sea level pressure is 1,013 millibars which is equal to 29.91 inches of mercury and 14.7 pounds per square inch. Obviously the pressure must decrease with increased elevation, for as one goes up in the atmosphere a greater part of the total column of air is left below. A consequence of this idea is that if the air is more dense in one place than in another, the pressure will decrease more rapidly with height where the denser layer of air is more concentrated near the ground. Thus pressures at equal levels aloft are usually higher where the air is warmer (or less dense) below that level, and lower where the air is cooler (or more dense).

Temperature.—Air temperature is a measure of

the thermal state of the atmosphere. Two temperature scales, the Fahrenheit and the Centigrade,* are in use in recording meteorological data. On the former scale, 32° is the freezing point of water and 212° the boiling point (at standard atmospheric pressure—1,013 millibars). On the Centigrade scale, 0° is the freezing point and 100° the boiling point.

Wind.—Wind is air in motion. Both speed and direction of the wind are observed. The direction always refers to the point of the compass from which the wind is blowing. Speeds are expressed in miles per hour, knots, or meters per second. Winds at the surface are usually gusty and changeable while winds aloft generally blow more steadily. Wind also includes a vertical component at all levels above the ground, which is generally much smaller than the horizontal component considered here. The vertical wind velocity is difficult to measure.

Humidity.—This refers to the amount of water vapor, exclusive of condensed water, in the atmosphere. Air has a greater capacity for water in vapor form at higher temperatures. As air is cooled and/or lifted this capacity is reduced, and if allowed to continue long enough, the air will reach a point beyond which it will no longer be able to hold its original amount of water in vapor form. This is known as saturation and if the temperature is lowered below this point, the excess vapor condenses into liquid water or ice. For most purposes of daily life, the *relative humidity* is the quantity used to express the condition of the air with respect to water vapor. It is defined as the percentage of saturation. Other measures of humidity in use are the dew point, which is the temperature to which air must be cooled at constant pressure in order to become saturated, and mixing ratio, which is the amount of water vapor present per unit mass of dry air.

Condensation Forms.—Water vapor condenses at saturation, forming dew or frost on the ground or on objects in the air, and fog or cloud in the air. (Fog is merely a cloud whose base rests on the ground.) Clouds and fogs usually consist of water droplets, even at temperatures below freezing in a supercooled state. At very low temperatures, however, the fog and cloud particles more frequently consist of small ice needles. Condensation forms which fall out of the air to the ground constitute *precipitation.* Precipitation falls when the water or ice particles become too large to float freely in the air. Precipitation occurs in many forms, the most frequent of which are rain, drizzle, snow, sleet, and hail. (See also Clouds, Dew, Fog, Frost, Rain, Rain-making, Snow.)

Visibility.—This is the horizontal distance at which prominent objects are visible. The observed visibility defines the degree of fog, smoke, dust, or haze which is present in the atmosphere. Visibility is also reduced by snow, rain, and drizzle.

Ceiling.—This refers to the vertical visibility as determined by the height of the cloud base. Ceiling is defined strictly as the lowest height at which the sky is more than one half obscured, including all clouds at or below that level. However, if the sky is one half or less overcast, the ceiling is defined as unlimited. Ceiling and visibility are of greatest importance in aircraft operations, especially in takeoffs and landings.

Meteorological Instrumentation.—To provide an adequate three-dimensional picture of the atmosphere the meteorological elements just mentioned must be observed at many points on the Earth's surface, at many levels above the surface, and at regular intervals each day. The human observer plays an important part in making these observations, but improved instrumental techniques have made man's observations more exact and have tremendously broadened the scope of the probing of the atmosphere. The standard meteorological instruments used for measuring temperature, pressure, humidity, rainfall, and wind at the Earth's surface are well known, and are discussed in detail in other volumes of The Encyclopedia Americana (see Anemometer, Barometer, Hygrometer, Rain-Gauge, and Thermometer). A brief discussion of a few notable advances in instrumentation will be given here with emphasis on instruments for upper-air observations.

Temperature, pressure, and humidity of the upper air are now generally measured by the radiosonde, a small lightweight instrument carried aloft by a large balloon filled with helium or hydrogen. The radiosonde contains an aneroid barometer, a resistance thermometer, and a hygrometer. These are connected to a very small radio transmitter so that signals giving pressure, temperature, and humidity values at various levels are broadcast by the instrument as it ascends. These signals are received and recorded at the station from which the balloon was released. In earlier years upper air soundings were made by kites (until about 1930) and then airplanes. By 1939 the airplane ascents were in turn almost completely replaced by the radiosonde in the United States. However, airplane observations have been used extensively during and since World War II in probing the atmosphere over vast ocean regions and remote land areas where meteorological stations are scarce. Aircraft reconnaissance has done some of its most notable work in polar regions, and over the tropical oceans where tropical storms have been located and closely tracked. Since the close of World War II rockets have been used to provide direct observations of the higher atmosphere (up to 135 miles). These have been experimental in nature and very infrequent.

Measurement of upper winds in clear skies or below clouds has been accomplished by observing the movements of an ascending small pilot balloon (pibal) with the aid of a theodolite. The development and application of radar and radio direction-finding since the late 1920's have made possible the tracking of balloons through and above clouds and fog and up to as high as 10 to 15 miles. These radio wind observations which are called "rawins," are made on a routine basis at many stations, but pibal observations still (1951) remain the predominant means of upper-wind measurement.

Radar, in addition to its use in winds-aloft determination, has since World War II become a powerful meteorological tool in several other ways. It is important in aircraft reconnaissance where absolute altitude can now be determined in conjunction with pressure measurements. It is also interesting that the very phenomenon (the blanketing of the echoes of man-made targets by precipitation and clouds) which at first hampered

* The term "Celsius" was officially adopted in place of Centigrade by the Ninth General Conference of Weights and Measures in 1950.

the operation of radar for its original purpose now provides the basis for many meteorological uses. Water drops in the atmosphere reflect radar pulses so that echoes can be obtained from clouds and precipitation. Thus, radar can reveal the position, direction of motion, structure, and intensity of clouds and rainfall associated with showers, thunderstorms, squall lines, fronts, hurricanes, and tornadoes at horizontal distances up to a few hundred miles. It also appears that it will soon be a means of obtaining a far better space integration of rainfall intensity and amount than can be given by widely scattered rain gauge measurements. (See RADAR for a full discussion of its development and operation.)

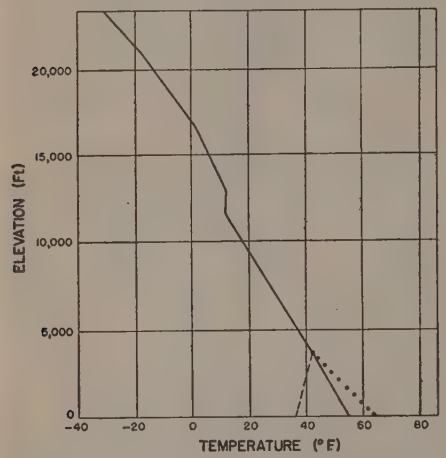

FIG. 1.—Typical vertical sounding of the atmosphere taken at 10 A.M. early in May at a station in the northeastern United States. Appearance of lower portion of sounding at 7 A.M. is indicated by dashed line and at 3 P.M. by dotted line.

Composition of the Atmosphere.—Air is a mixture of ten different gases. Aside from water vapor, this mixture is nearly the same throughout most of the atmosphere, with nitrogen (78 per cent) and oxygen (21 per cent) predominating. Between 12 and 25 miles above the Earth's surface much of the oxygen appears as ozone which absorbs part of the ultraviolet radiation from the Sun. Argon and carbon dioxide are also of significance but make up less than 1 per cent of the mixture. Water vapor is the one gas which is quite variable, ranging from a trace to as much as 4 per cent at some places on hot, humid days. According to William J. Humphreys, if all the water vapor were condensed out of the atmosphere, it would cover the entire earth with water about one inch deep. The atmosphere also holds in suspension minute particles of many solid substances such as dust, smoke, salt, and pollen. These are picked up from the underlying surface of the Earth and thus are most significant in the lower levels of the atmosphere.

Extent of the Atmosphere.—As any layer of air is compressed by overlying layers, it follows that the layer at the surface is densest. Accordingly, air becomes lighter and lighter with increasing elevation. There can be no definite upper limit to the atmosphere, but probably above an elevation of more than about 600 miles the atmosphere gradually becomes as highly rarefied as the gases in outer space. It has been calculated that at an elevation of about 21,000 miles the force of gravity can no longer hold the air particles and that they fly freely out into space. In spite of its great depth, half of the atmosphere is contained within only the first 3.5 miles above the surface since pressure drops off so rapidly with elevation. If the atmosphere had the same density throughout as at the surface, it would form a layer only 5 miles high. (See also ATMOSPHERE.)

Heat Balance of the Atmosphere.—Heat for the atmosphere originates on the Sun, the amount received being enormous. It has been calculated that the solar energy received by the Earth per minute is equal to the burning of 100 million tons of soft coal.

The air is practically transparent to the incoming solar radiation (unless there is a cloud cover) so that most of the energy is received directly at the Earth's surface without much heating of air. A considerable part of this solar energy is directly reflected to space from the Earth, the amount depending upon the reflective character of the Earth's surface (water, forest, desert, etc.). The remainder is absorbed by the surface. The Earth then contributes heat to the air in several ways. First the Earth reradiates some of its heat energy, but at longer wavelengths than those received from the Sun. Many of these longer waves are more readily absorbed by the water vapor of the atmosphere, although a substantial part of this terrestrial radiation passes directly out to space again. The Earth also heats the air by conduction combined with convection. When air is cooler than the Earth, the layer immediately in contact with the ground is heated by conduction. Since air is a very poor heat conductor, other layers somewhat removed from the surface would not be affected solely by conduction. However, it is the heated layer of air adjoining the ground which transports the heat to higher levels and distant portions of the atmosphere. This occurs as the heated air, becoming lighter than adjacent bodies of air, is forced to rise by virtue of its buoyancy, and then flows off horizontally aloft. This convection process transfers heat both horizontally and vertically at a much more rapid rate than radiation. Water vapor also plays an important role in transferring heat from the Earth's surface to the atmosphere. Evaporation of water from the Earth's surface into the air takes place at the expense of a certain amount of the surface's heat content. The water vapor carrying this latent heat is diffused through the atmosphere by the winds. Eventually the water vapor condenses again mostly in the form of clouds and precipitation, thus releasing the latent heat of condensation to the atmosphere aloft.

Since the Earth and its atmosphere, as an entity, do not become progressively colder or warmer, it is apparent that there must be a balance of the heat received by radiation from the Sun and that lost by the Earth and air. Most of the incoming solar radiation is absorbed in tropical regions, while much smaller amounts are received in polar regions. But since much of the heat received in equatorial regions is transferred by the air and the oceans to higher latitudes, the outgoing radiation from the Earth and the air does not vary appreciably with latitude.

Distribution of Temperature.—*Surface Air*

Temperatures.—It follows from the considerations of the heat balance just mentioned that temperatures at the Earth's surface are warmest in equatorial regions and coldest at the poles. However, the distribution of land and water and the presence of ocean currents and winds make the temperature distribution over the Earth much more complex. Land and water at the same latitude, exposed to the same amount of solar radiation at a given time, may have markedly different temperatures because of their differing absorption properties. Land very readily absorbs nearly all of the radiant energy received, but it is all concentrated within a few centimeters of the ground surface. Thus, temperatures of land rise rapidly as heat is received, and likewise drop rapidly as heat is lost. On the other hand, the heat received by water is distributed through a rather deep layer so that the surface temperature rises slowly. When the water surface cools, warmer water is constantly transported upward, as the cooler water sinks to greater depths. Therefore, the surface temperature of water decreases rather slowly as the surface cools. As a consequence of the difference between land and water, it is found that surface air temperatures over continents are considerably colder than those over the oceans in winter, and considerably warmer in summer.

Vertical Distribution of Temperature.—The temperature in the atmosphere generally decreases with height above the Earth's surface until it reaches on the average about —50°F. at 6 miles above the Earth in polar regions and about —100°F. at 11 miles in equatorial regions. Above these levels the temperature remains nearly constant in polar regions while it rises with height in equatorial regions. The level at which the temperature decline ends is called the *tropopause.* Below the tropopause is the *troposphere,* where the temperature drops with height, and above is the *stratosphere,* where the temperature remains the same or increases with height.

Direct observations of the upper air by sounding balloons have become frequent only since the 1930's. Soundings of the atmosphere regularly reach heights of 10 to 15 miles. Some comparatively rare observations by rockets have been made since the 1940's up to 135 miles. Thus, temperatures above 15 miles are known largely from indirect evidence such as meteor observations, abnormal sound wave propagation, noctiluscent clouds, aurorae, and radio beams. From all available evidence it is believed that temperatures increase from the lower stratosphere upward to about 100°F. at 35 miles, decrease again to about —100°F. at 45 to 50 miles, and then increase again to about 1,300°F. at 190 miles.

Temperature Lapse Rate.—The rate at which temperatures decrease with elevation is called the vertical temperature gradient, or temperature lapse rate. In the troposphere the lapse rate is about 3°F. per 1,000 feet. An example of an atmospheric sounding is given in Fig. 1. This shows how the lapse rate varies in different atmospheric layers at the given time and place of this sounding. The sounding was taken at 10 A.M. The estimated appearances of the curve at 7 A.M. and at 3 P.M. are shown by the dashed and dotted lines to illustrate the difference in the sounding between the warmest and coolest parts of the day at the surface.

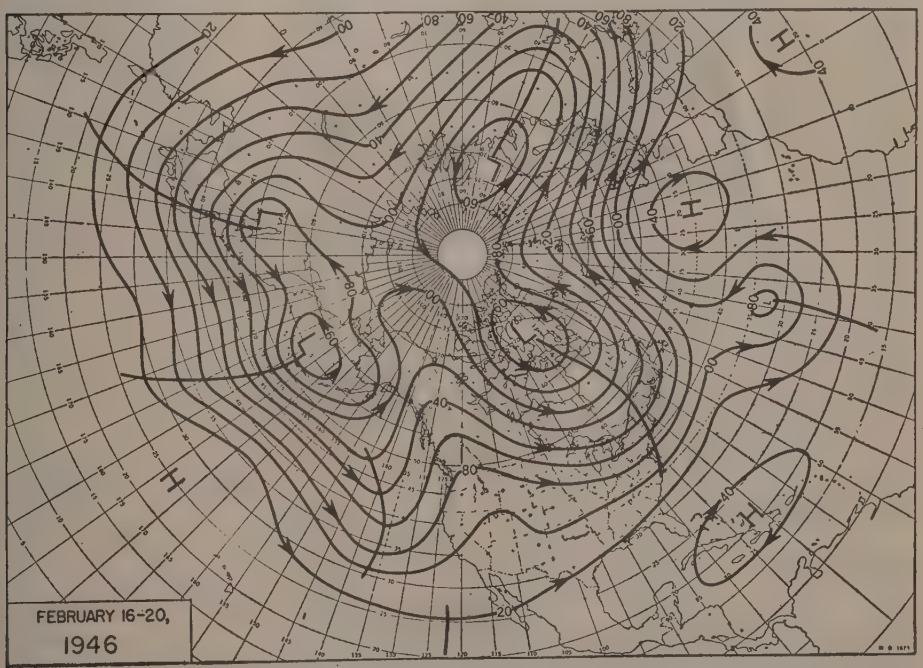

FIG. 2.—Average 700-mb constant pressure chart for a five day period. This is an example of the winter circulation around the Northern Hemisphere between about 8,500 and 10,500 feet above sea level. Air flows in the directions indicated along the contour lines at a speed inversely proportional to the spacing of the lines. H indicates high center, L is low center.

Adiabatic Process.—If a parcel of air is heated at the surface it is usually forced to rise because it has expanded and is therefore lighter than the surrounding air. In rising it further expands and we have the process known as *adiabatic cooling*. This refers to the cooling of a parcel of ascending air without the gain or loss of heat from or to air outside the rising parcel. In the case of unsaturated air, the rate of cooling of this parcel through the surrounding atmosphere is 5.5°F. per 1,000 feet. (The lapse rate prevailing in the surrounding air which was discussed in the previous section may or may not be the same as the cooling rate of this rising parcel, which is called the dry adiabatic lapse rate.) Conversely, if unsaturated air descends it warms at the same dry adiabatic rate.

If an air parcel is lifted and cooled beyond its saturation point, water begins to condense out of the air. As condensation takes place, latent heat is released as a result of the change of state from gas to liquid or ice. So, as a parcel ascends above the condensation level, it cools more slowly than when it was unsaturated. This moist or pseudo-adiabatic lapse rate has no constant value since it varies with the amount of moisture being condensed. When precipitation drops out of the rising air it is obvious that its total moisture content (vapor, liquid, and solid) decreases during the lifting. In this case, if the air descended again, it would drop for a much shorter distance at the moist adiabatic rate than on its way up. It would then continue its descent at the dry adiabatic rate and return to its original level at a higher temperature than it had at the beginning. This effect is often observed when moist air

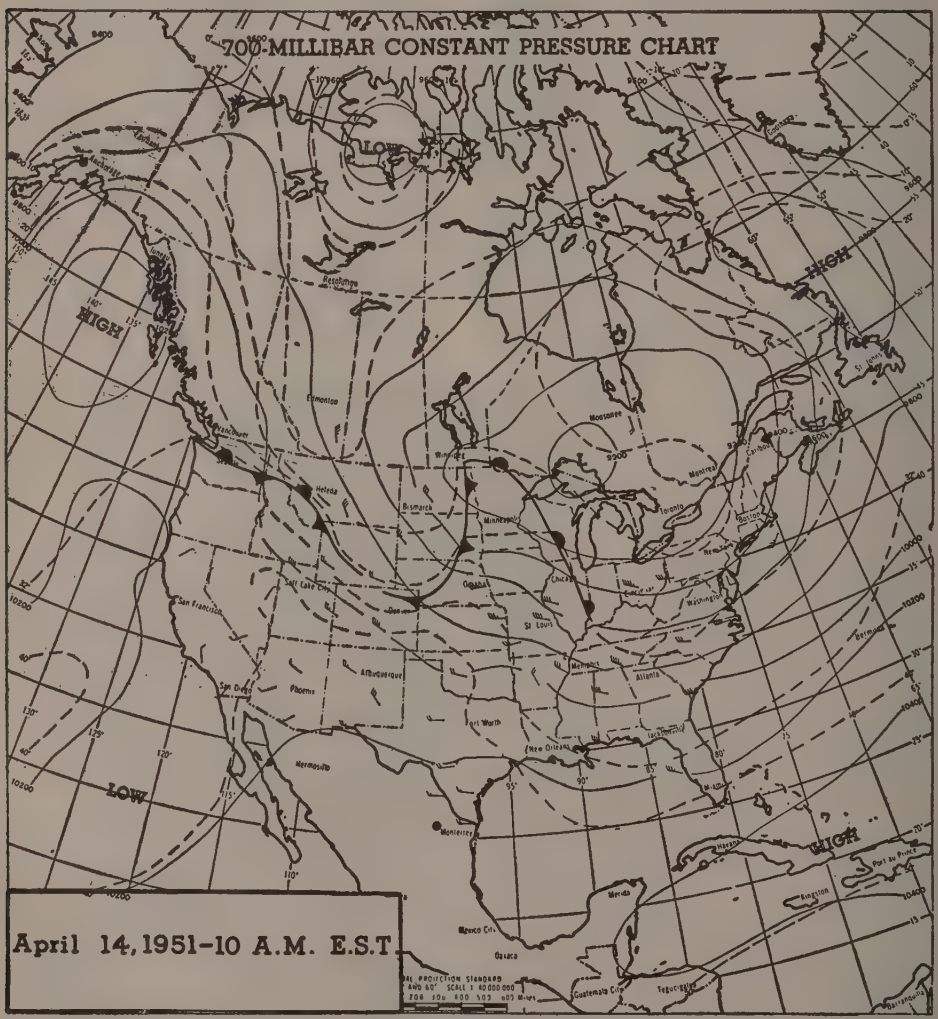

FIG. 4.—Upper level chart based on observations made 3½ hours earlier than those used for the sea level chart in Fig. 3. Thin continuous curved lines are height contours along which the air generally flows. Arrows show observed wind direction with the number of barbs indicating strength of flow (each full barb represents about 10 miles per hour). Dashed lines show temperatures in °F. at 10° intervals. These charts are usually prepared twice daily from radiosonde observations.

flows over a mountain. As it is lifted on the windward side the air cools, and rain or snow falls out up to the top of the mountain. Then, as the air descends on the leeward side, it warms at the dry adiabatic rate, returning to its original level at higher temperatures than it had before it ascended the mountain. This is in part the explanation of the warm dry chinook or foehn winds observed on the leeward slopes of the Rocky Mountains and the Alps.

Vertical Stability of Air.—The lapse rate of the air existing at a given time and place determines the degree of stability of the air in the vertical. If the lapse rate is such that a parcel or layer of air resists upward or downward displacement, the air is stable. But if the lapse rate is such that an air parcel or layer will rise or sink of its own accord, once given an impulse, the air is unstable.

Stable air is characterized by a vertical temperature gradient or lapse rate which is less than the dry or moist adiabatic lapse rate, depending upon whether saturated or unsaturated conditions exist. Under stable conditions a lifted air parcel would soon find itself at a lower temperature than its surroundings since it cools at the adiabatic rate. Since this parcel would now be denser than the surrounding air, it would have to sink back to its original level. Thus, vertical motion is resisted and the air is stable.

Unstable air is characterized by a vertical temperature gradient or lapse rate which is greater than the dry or moist adiabatic lapse rate, once again depending on whether saturated or unsaturated conditions exist. In this case a lifted air parcel would cool at the adiabatic rate, which is not as much as the prevailing rate in the surroundings, and would soon find itself at a higher temperature than its surroundings. Since the parcel would now be less dense than the surrounding air, it would continue to rise, becoming at an ever increasing rate warmer than the adjacent air, as long as the prevailing lapse rate remains steeper than the adiabatic. Thus, vertical motion is accelerated and the air is unstable.

When a substantial amount of unstable air rises all at once in a convective updraft, such as exists in the familiar thundercloud, the air parcels do not simply rise without disturbing the adjacent layers of air. Rather a considerable amount of the cooler, drier air surrounding the updraft is pulled along or "entrained" with it. As this happens, the moister and warmer air coming up from lower levels mixes with this entrained air, and the result is that the air at higher levels in an updraft is cooler and less moist than would be expected from the simple adiabatic cooling of a parcel or layer discussed above.

The degree of stability or instability of the air has several consequences since it reflects the susceptibility of the air to vertical motions. For one thing unstable air with its inclination toward vertical motion generally results in rather bumpy or turbulent flying conditions while stable air is ideal for rather smooth flying conditions. Also, clouds associated with unstable air are of the cumuliform (vertically developed) type while stratiform (flat layer type) clouds are favored where stability prevails. Air must be markedly unstable, of course, for the development of cumulus-type clouds into the large swelling cumulus or cumulo-nimbus which produce showers, thunderstorms, and tornadoes. Of ever increasing importance is one other consequence of stability. This is its role in facilitating or obstructing the removal of the combustion products of industrial plants and other sources from the layers of air near the Earth's surface. When instability prevails in the air within about a thousand feet of the ground the turbulent vertical motions rapidly diffuse the smoke emitted from stacks through a large volume of air. When the air is stable, however, and turbulent vertical motions are suppressed, these combustion products are concentrated near the ground and have little chance to escape. Pollution becomes most acute when a large temperature inversion exists in the surface layers for several days. This is likely to occur in connection with a stagnant high pressure cell (anticyclone). The very severe effects of such a condition were felt on October 30-31, 1948, when 20 persons died and hundreds of others were stricken in and near Donora, Pa.

Wind and Pressure.—The speed of the wind is largely a function of the horizontal difference in pressure between two places. The greater the difference in pressure, the stronger the wind. It would seem logical for air to flow directly from high pressure toward low pressure, but this is not the case on the rotating Earth. The rotation of the Earth produces an apparent deflecting force, which in the Northern Hemisphere turns air currents toward the right. Thus, air flowing from high to low pressure is turned to the right until the deflecting force balances the force of the pressure difference, or the pressure gradient force. Air flows nearly parallel to the lines of constant pressure, or isobars, with high pressure to the right and low pressure to the left. (These directions are all reversed in the Southern Hemisphere since the deflective force acts toward the left.) At the surface, the friction of the ground retards the air and allows the pressure gradient force to overbalance the deflective force so that the air blows at a small angle (20° to 30°) across the isobars toward lower pressure.

General Circulation.—Measurements have shown that the heat received by solar radiation in equatorial and tropical regions is greater than that radiated to space in those regions, while the heat received from solar radiation in polar regions is less than that radiated. This means that there must be a transfer of heat from the tropical to polar latitudes. To effect this transfer there must be a primary or general circulation of the air over the Earth. This circulation is rather complex due to the Earth's rotation, the unequal distribution of land and water, and the effect of mountain barriers over which the air must travel. Many features of the general circulation are known through observations, and some of these will be discussed here.

The observed general circulation of the atmosphere may be portrayed by long period average, or normal, pressure maps for various months of the year at both sea level and aloft. Since the winds generally blow along the isobars and at a speed inversely proportional to the spacing of isobars the circulation is readily portrayed by the pressure field. For example, a chart of the normal pressure distribution over the Northern Hemisphere at sea level for a winter month reveals certain large cellular high and low pressure areas, generally known as centers of action. These are the Icelandic and Aleutian lows, the

Atlantic and Pacific, subtropical high cells, and the North American and Siberian highs. The circulation around the Icelandic low, for instance, comes from the north out of eastern Canada, turns eastward across temperate latitudes of the Atlantic, flows across northern Europe towards the northeast, turns poleward in the Siberian Arctic, and then flows westward across the Arctic Ocean and northern Greenland back to northeast Canada. From such a chart one may obtain the average airflow around the hemisphere in a west-to-east or east-to-west direction. When this is done, it is found that in January this flow is prevailingly from the west (westerly) in temperate latitudes and from the east (easterly) in polar and subtropical latitudes. Average pressure maps at higher levels (from 10,000 to 50,000 feet) become somewhat simpler since higher pressure appears over the warmer regions and lower pressure is found over colder areas. Thus, in winter at higher levels the easterly winds largely vanish and there exists a vast whirl of westerly winds surrounding the pole. In summer the individual features at sea level and aloft mentioned here change somewhat, so that circulation is less intense and the upper level westerlies shift farther north.

The large-scale general circulation around the hemispheres also exists on shorter period average maps or on a daily map. At most times, at levels between 10,000 and 50,000 feet, there are narrow zones of strong winds (sometimes reaching a maximum of about 250 miles per hour near the tropopause level) in the "westerly whirl." These are known as *jet streams.* The jet stream and its accompanying westerly current are by no means straight westerly, but actually the flow has the appearance (from a perspective of the entire hemisphere) of a meandering river moving to higher latitudes in some areas and to lower latitudes in others. A picture of such a flow pattern at the 700-millibar pressure level (about 10,000 feet) is shown in Fig. 2. This is an average map for five days. Lines connecting northernmost points of the curving contours of the westerlies are called *ridges,* and lines connecting southernmost points are *troughs.* (The latter are drawn as heavy lines in Fig. 2.) Together these troughs and ridges constitute "waves in the westerlies." The wavelengths (measured in terms of distance from trough to trough) usually vary from about 2,000 to 4,000 miles. The individual waves in this circumpolar belt are strongly interdependent. Cold air masses from polar latitudes are brought into the troughs by the northwesterly flow behind them, while warm air from the subtropics travels northward in the southwesterly flow ahead of the troughs and into the ridges. Each trough is generally associated with one or more of a family of cyclones at sea level, and each ridge with a sea level anticyclone. This association can be seen by comparing the sea-level and upper-level maps in Figs. 3 and 4. The upper-level current generally exercises a steering effect on the surface air masses, fronts, and storms, which will be discussed below.

Air Masses.—An air mass is defined as a large portion of the atmosphere which is homogeneous as to temperature and humidity in its horizontal layers over an extensive area of the Earth's surface. If a body of air lies or travels over a particular region of uniform surface and great extent, such as a large land area or a broad ocean, it will acquire properties of temperature and humidity peculiar to that area. Thus a mass of air over a northern continent will be cold and dry in distinct contrast to air over a tropical ocean which will be warm and moist. As an air mass moves from its source region, it begins to modify in response to the surface it traverses at a rate which is relatively slow. An exception to this is when cold, dry air in winter moves out over a warmer ocean surface. In this case the air mass absorbs heat and moisture rather rapidly, developing into a different type in less than a day.

Air masses are classified according to their primary source region, either polar or tropical. They are further classified as to whether they are maritime or continental in character. Consequently, there are essentially four different air masses, continental polar (cold and dry), maritime polar (cold and moist), continental tropical (warm and dry), and maritime tropical (warm and moist). Continental polar air in the Northern Hemisphere originates over the northern continents and the ice- and snow-covered Arctic Ocean. Maritime polar air has its source in northern portions of the Atlantic and Pacific oceans. Maritime tropical air comes from the tropical and subtropical latitudes of the Atlantic, Pacific, and Indian oceans, the Mediterranean and Caribbean seas and the Gulf of Mexico. The subtropical continental areas produce continental tropical air. These areas include the southwest United States and Mexico, the Sahara, and large portions of the Near and Middle East. The properties of the air masses change with the changing properties of source regions from season to season. In temperate latitudes the air masses often alternate (with warm air masses extending their influence farther and farther north as summer approaches) so that the weather may be warm and balmy one day while maritime tropical air is present, and cold and blustery the next day, as continental polar air invades the area.

Fronts.—When two dissimilar air masses are brought together by the general atmospheric circulation they do not immediately mix, but a definite boundary or *front* (perhaps 5 or more miles wide) occurs between them. Along and near this front colder (denser) air generally underlies warmer (rarer) air in the form of a wedge so that the front is usually inclined at a small angle to the Earth's surface. A *cold front* is the boundary between the forward edge of an advancing cold air mass which is displacing warmer air in its path by underrunning the latter. A *warm front* is the boundary at the forward edge of an advancing current of relatively warm air which is displacing a retreating mass of cold air, in which case the warm air overruns the cold mass. These fronts are often characterized by rather definite air-mass interactions, such as variable winds, clouds, rain, rather abrupt temperature changes, and other weather phenomena. The form and intensity of these interactions depend on the differences in characteristics of the air masses involved, their extent, and the amount of converging motion forcing them together. The major cloudiness and precipitation associated with fronts are produced by the cooling and saturation of the warm air mass as it is forced upward over the colder air mass.

Cyclones and Anticyclones.—*Extratropical Cyclones.*—These are the general storms of temperate latitudes. The great majority of these

Sagging telephone wires and broken tree branches tell the story of layer upon layer of ice accumulated during a severe ice storm in upper New York State.

storms develop as small waves along slow moving or nearly stationary fronts between two differing air masses. This initial wave disturbance causes a thrust of warm air toward the cold air at one place (warm front) followed by a thrust of cold air toward the warm air (cold front) at another place. If certain conditions of air mass contrast, wind discontinuity, wavelength, and upper flow pattern are met, this wave begins to develop into a full-scale extratropical cyclone. The warm front pushes far to the north and the cold front pushes far to the south as the wave moves (generally eastward), steered by the westerly flow aloft. The average speed of these waves is about 35-40 miles per hour in winter and about 20-30 miles per hour in summer. The storm development is accompanied by lowering pressure at the crest of the wave, or cyclone center, and by increasing winds circling the storm in a counterclockwise direction (in the Northern Hemisphere). Generally the cold front moves more rapidly than the warm front so that the former begins to overtake the latter while the storm is still in its intensifying stage. This *occlusion* process lifts the warm air completely off the ground and the cyclone soon becomes a whirling mass of cold air. As this occurs the storm gradually begins to decay. At its greatest intensity the storm may have a diameter of as much as 1,000 miles.

The huge cloud and precipitation systems of these great extratropical cyclones are representative of frontal weather in its most pronounced form. Ahead of the warm front there is usually a large area of steady precipitation caused by the gentle upglide of the warm air. Along the cold front there is a long, narrow band of heavy, showery precipitation caused by the forced lifting of the warm air.

Tropical Cyclones.—These storms occur within the tropical air masses, and are most frequent in western portions of the tropical Atlantic and Pacific oceans from August to October. Other common names for the tropical cyclone are *hurricane* and *typhoon.* In the Northern Hemisphere hurricanes form over the oceans at about 10° to 20° N. latitude where there is a plentiful supply of heat and moisture. They generally travel westward in the trade wind belt. Very often they curve northward at the western edge of the subtropical high cell and reach into temperate latitudes. Here they either dissipate or become extratropical cyclones. These storms are usually only about 100 to 200 miles in diameter, but they are characterized by destructively strong winds (often 150 miles per hour at the surface), torrential rainfall, incessant lightning, and very low central pressure. In addition the strong winds generate large waves and high tides which inundate low-lying coastal areas exposed to the onshore flow of the storm.

Anticyclones.—These are high pressure systems which are generally characterized by clear skies and gentle winds. They usually mark the centers of air masses, and may be cold polar air highs or warm tropical air highs. They are in contrast to the extratropical cyclones which mark the meeting ground of two or more dissimilar air masses. Cold anticyclones in middle latitudes are generally transported eastward under the westerly upper-level flow. Warm highs in the subtropics and cold highs in the arctic are slow-moving or stagnant.

Local Storms.—*Thunderstorms.*—These are the familiar local storms which are accompanied by lightning, thunder, strong and gusty surface winds, heavy rain, and sometimes hail. They are usually of short duration (less than 2 hours) and are only of limited horizontal extent (8-12 miles in diameter). Vertically these storms often extend from a few thousand feet above the ground up to 30,000 feet or more. The typical towering cumulo-nimbus or thundercloud is produced by vigorous upward motion resulting from well-marked vertical instability of the air. After the cloud is well-developed, extensive downdrafts, which are associated with large falling raindrops or hail, set in. These cool downdrafts spread out from the storm's center as they approach the ground. Thunderstorms are most frequent in regions where warm moist unstable air masses predominate. Frequently thunderstorms are found in long lines several hundred miles in length. These are known as *squall lines* and often occur along or preceding a cold front.

Tornadoes.—These are the most violent storms known. They develop in connection with severe thundersqualls where extreme instability of the air is present. The tornado consists of a whirling mass of air of small diameter (between about 300 and 3,000 feet) with an intense rotation. The most spectacular visual characteristic is the funnel-shaped cloud which frequently descends to the ground. The wind speeds in the tornado have never been accurately measured (wind instruments do not survive the blast), but it is estimated from their destructive effects on solid structures that they exceed 300 miles per hour. Fortunately it is usually a short-lived storm lasting from a few minutes to an hour.

Forecasting.—The ultimate goal of most meteorological knowledge and research is the improvement of weather forecasting. Although innumerable advances in the science of meteorology have been made in the first half of the twentieth century, weather forecasting is still much dependent upon empirical methods. However, even though rigid scientific methods are largely lacking, increasing application of theoretical principles to weather prediction is taking place.

The general problem of forecasting weather conditions may be broken down into two major phases. One is the prognosis of the expected state of motion of the atmosphere at some time in the future. The other is the problem of interpreting this state of motion in terms of weather it will produce at various points.

The first phase of the problem involves primarily a thorough diagnosis of the existing state of the atmospheric circulation and associated meteorological elements over a considerable portion of the Earth, both near the surface and aloft. For the short-range forecast (up to 48 hours) the area involved may be a continent and large sections of adjacent oceans as in Figs. 3 and 4. For the long-range forecast (more than two days) in the Northern Hemisphere, for example, the area should cover practically the whole hemisphere as in Fig. 2. This means that the forecaster is dependent upon a great deal of international cooperation to provide him with weather data, and to help him obtain more adequate data in the future. Once the current state is known the problem is to secure an estimate of how the atmospheric motion will change from the present to a specified future time. To do this the laws of fluid mechanics and thermodynamics, which are

generally known, should be applied. But since the Earth-atmosphere system is so complex, the problem of solving the necessary equations is very difficult even when many simplifying assumptions are made. The development and use of high-speed electronic computing machines in the 1940's and early 1950's promises to provide the forecaster with some practical solutions to this problem in the near future. However, even if this proves feasible, the complete solution of this phase of the problem without simplifying assumptions seems a long way off since so many of the physical factors involved are so poorly known or understood. Meanwhile the forecaster makes use of many hydrodynamic principles in prognosticating the motion and development of waves in the upper-level westerly flow and the associated cyclones, anticyclones, air masses, and fronts of the surface map. To the indications of these principles he adds the results of application of purely kinematic and empirical methods, and arrives at a circulation forecast.

The second phase of the problem is to forecast the weather from the expected circulation. Here again certain theoretical principles are applied. For example, from the cyclone theory of Vilhelm Bjerknes and others, a certain distribution of precipitation, cloudiness, and temperature around a cyclone in relation to cold and warm fronts is expected. In the 1940's the development of statistical forecasting techniques, which summarize the relation of the circulation to the weather elements for past data, has begun to provide a substitute for long forecasting experience.

It is expected that forecasting will continue to become more of a purely scientific procedure in the future as meteorological research makes further discoveries about the complex workings of the atmosphere.

JAY S. WINSTON,
Meteorologist, United States Weather Bureau.

METEOROLOGY, Marine, differs from that of land areas chiefly from the fact that the rays of the Sun penetrate more deeply into the ocean substance than into the land and that the diffusion of this heat through the water body is practically uniform. The ocean thus becomes a vast storage reservoir of heat which is but slowly returned to the atmosphere. The effect upon the ocean climate is to render it more equable. METER, a mechanical device or instrument for automatically measuring, indicating, and recording the quantity measured.

Gas Meter.—This is an automatic instrument which measures the volume of gas flowing through a pipeline. There are two types: (1) the *wet meter,* in which a drum submerged in liquid is rotated by the entering gas; indicators geared to the axis of the drum indicate the amount of gas flowing through the instrument; (2) the *dry* meter, in which the gas entering the instrument displaces a piston, the extent of the displacement being shown on a dial.

Water Meter.—This mechanical device measures and automatically records the quantity of water flowing through a pipe. There are three types: (1) *positive,* which measures the actual volume of water; (2) *inferential,* which measures the velocity of the flowing water; and (3) *proportional,* which measures a fractional part of the full flow. See also CURRENT METER; WATER METER.

Electric Meters.—These instruments are designed to measure either electrical current or energy, or its potential, resistance, inductance, or capacitance. There are three general types of electric meters: (1) the *electrolytic* meter; (2) the *clock* meter; and (3) the *motor* meter. The latter is most generally used. For other types of meters see under AMPEREMETER; ELECTRICAL MEASURING INSTRUMENTS; ELECTRICAL TERMS; ELECTROMETER; GALVANOMETER.

METH. See MEAD.

METHANE, CH_4, is the first member of the aliphatic or paraffin series of hydrocarbons of the type formula C_nH_{2n+2}. It is a very stable and abundant substance, being the principal component of natural gas. The methane content of natural gas varies between 50 and 98 per cent, but is commonly nearer the higher value. A typical gas will contain around 85 per cent methane, up to 9 per cent ethane, 3 per cent propane, the remainder being higher hydrocarbons and nitrogen. This sample before distribution contained some low-boiling liquids which were removed and blended with petroleum distillates. Since methane is a product of the decomposition of vegetable matter, it is often called marsh gas. Pockets of methane are often found in coal deposits, and as firedamp, are a source of danger and the cause of numerous mine disasters. Methane is also evolved in certain sewage disposal processes and may be used as a source of heat and power.

In the carbonization of coal for the production of industrial and metallurgical coke a gas is formed which contains methane to the extent of 30 to 40 per cent. Carburetted water gas, made up mainly of carbon monoxide and hydrogen, owes its added heat value to 10 to 15 per cent methane, which results from the thermal decomposition of enriching oil. Since methane is practically always a product of the pyrolysis of hydrocarbons, petroleum refinery gases are rich in methane.

Pure methane may be prepared in the laboratory by heating dry sodium acetate with a mixture of caustic soda and quicklime, and by decomposing either methyl magnesium iodide or aluminum carbide with water. Both carbon monoxide and carbon may be reduced by hydrogen at high temperature to methane. Compressed methane is available in commercial cylinders, but the bulk of this gas is utilized as it is produced without separation from accompanying substances.

Methane is comparatively unreactive towards such reagents as nitric acid and sulphuric acid, but can be converted into a series of substitution

products ranging from methyl chloride, to carbon tetrachloride. However these substances are more commonly prepared by other methods so that mixtures of the four possible compounds are avoided. Methane is a common source of hydrogen, being acted on by steam in the presence of a catalyst, the accompanying carbon dioxide being scrubbed out from the hydrogen. A method of making so-called "synthesis gas" for the production of liquid hydrocarbons from natural gas involves the partial combustion of methane with commercial oxygen to carbon monoxide and hydrogen. Subsequent reactions carried out at high temperature in the presence of a catalyst result in higher molecular weight hydrocarbons and oxygenated derivatives. Methane and ammonia may be made to react to form hydrogen cyanide, a starting substance in the plastics industry. Acetylene may be made from methane either by thermal methods or by a low voltage electrical discharge, but neither method is in commercial operation. Methane and other hydrocarbons in natural gas are the source of various types of industrial carbon, the most important being "gas black" for the rubber industry.

The boiling point of methane is —161.7°C., hence it is rarely liquefied except when necessary to remove helium from the natural gas of the Southwestern states. Methane has no color nor odor and its density is approximately 0.56 that of air. Its heat of combustion is 1113 British thermal units (gross), the gas being measured at 60°F. and 30 inches barometric pressure. Methane forms explosive mixtures with air in proportions which range from 5.8 to 13.3 per cent.

METHOD OF LEAST SQUARES. See Least Squares, Method of.

METHODISM is a general name describing the practical religious movement of personal experience and social responsibility set in motion in the 18th century by the experience, preaching, hymn writing, and organizing genius of two British Anglican priests, John Wesley (1703–1791) and Charles Wesley his brother (1707–1788) (qq.v.).

The thirteen and one-quarter million Methodists in the world, two thirds of whom are in the United States, are loosely bound together in the Ecumenical Methodist Council, conferences of which met in London (1881), Washington (1891), London (1901), Toronto (1911), London (1921), Atlanta (1931), and Springfield (1947).

HISTORY

Oxford Beginnings.—At first strictly Anglican and rubrical, the movement began at Oxford University in November 1729 when John Wesley, returning from service under his father, Samuel Wesley (1662–1735), as a curate in Lincolnshire, joined a group of Christ Church students who were taking weekly communion with his brother Charles. At the time John was 26, Charles 22. The group, never exceeding 30, was bound together by personal influence and mutually agreed upon habits and usages including the common study of the Greek Testament, regular fasting, the observance of stated hours for private devotion, the visitation of the sick, the poor, and prisoners, and instruction of neglected children.

The name *Methodists* was one of a number of derisive epithets used to describe the group. Because it continued to be an accurate description, Methodism was finally accepted as the official name of the movement. A doggerel current at the time expresses the significance of the name like this:

> By rule they eat, by rule they drink,
> Do all things else by rule but think,
> Method alone must guide them all,
> Whence Methodists themselves they call.

The Aldersgate Experience.—While between 1733 and 1735 the first Oxford Methodism was becoming more patristic, John Wesley fell under the influence of William Law's devotional ideas most clearly expressed in his *Serious Call to a Devout and Holy Life* (1728). Wesley's spiritual experience was further advanced during his unsuccessful service as a missionary of the Society for the Propagation of the Gospel to the Indians in Georgia (Feb. 6, 1736, to Dec. 2, 1737) by his industrious translation of 33 hymns from the German into English and by daily contact with the Moravians in their joyful faith, their earnest prayer, and in their conviction of the merits of the religious method of justification through faith. In Georgia the young priest sang in his own translation Dessler's words: "Into Thy gracious hands I fall and with the arms of faith embrace: O King of Glory, hear my call! O raise me, heal me by Thy grace!" Returning to London, Wesley suffered from disappointment over his spiritual ineffectiveness in the new world, disaffection resulting from a love affair, and spiritual unrest kindled by his contact with the Moravians. Influenced especially by the Moravian Peter Böhler to alter his belief that religion was only an intellectual and moral habit, that is, a methodical union of intellectual belief, voluntary self-submission, and punctilious performance of the routines of the Church and the general duties of life without concern for the intervention of the supernatural and divine in life, Wesley wrote on March 5, 1738: "By Peter Böhler in the hands of a great God I was fully convinced of the want of that faith whereby we are saved." The text "if any man be in Christ, he is a new creature" increasingly expressed the object of Wesley's quest to be born again.

On May 24, 1738, at the end of a day of earnest spiritual seeking, Wesley, dressed in the habit of an Anglican priest, sat down in a prayer meeting being held in a secluded room on Aldersgate Street, London. He listened to a layman reading aloud Luther's *Preface to the Epistles to the Romans*. Of the ensuing experience, Wesley says: "While he (Luther) was describing the change which God works in the heart through faith in Christ, I felt my heart strangely warmed. I felt I did trust in Christ, Christ alone, for salvation; and an assurance was given me that He had taken away my sins, even mine, and saved me from the law of sin and death." This experience of the "heart strangely warmed" became a motivating religious experience characteristic of Methodism. Among Methodists this *day* of the *Aldersgate Experience*, May 24, 1738, and the *hour* of "quarter to nine" identify a vivid, dated conversion. William E. H. Lecky in his *History of England in the Eighteenth Century* (1882)

calls the experience on Aldersgate Street an *"epoch in English history."*

The Evangelical Mission.—Following the Aldersgate Experience and after a visit to the Moravian center at Herrnhut on the continent, Wesley, feeling now the assurance of salvation through Christ, began his life mission. During the 53 strenuous years which followed he preached some 40,000 sermons and traveled a quarter of a million miles, mostly on horseback, keeping a detailed journal which literally is a guidebook of the British Isles.

The Wesley who emerged from Aldersgate and Herrnhut preached a gospel of a "new birth" by which men became "new creatures." This new birth depended neither on churchly form, creed, priestly prerogative, sacramental grace, or influence; it was the free gift of God's grace to repentant men. Wesley came to have one dominating objective: by preaching and personal influence to raise up a body of converted men who themselves would become witnesses to truth by which he had been saved. Under this inspiration he preached a persuasive gospel; as a consumate organizer he formed living witnesses into classes and societies. *Preaching power in the pulpit and private and personal influence in the class room became the two characteristic forms of Methodist activity. The power-link between the pulpit and the class meeting was the doctrine and experience of conversion.*

A word needs to be said about John Wesley's effective method of preaching. He spoke in short, economical phrases, using his eyes in such a way that each person in the congregation felt himself alone pierced and knew that the words were meant especially for him. Three of Wesley's simple observations about Christian method may help to explain his practical and direct program for Christian living.

1. "Read and meditate upon the 13th chapter of the 1st *Epistle to the Corinthians.*"

2. "If we see God in all things, and do all for Him, then all things are easy.

3. *"Do all the good you can, by all the means you can, in all the ways you can, in all the places you can, at all the times you can, to all the people you can, as long as ever you can."*

Evolution of a Church.—The unsectarian evangelical efforts of John and Charles Wesley and their associates were in reality the activity of another sect in process of formation as a church. When established churches closed their doors to him and clergy took offense at his doctrines, Wesley in 1739 took recourse, as his Oxford friend, George Whitefield (1714–1770), was already doing, to preaching in the open fields to immense crowds and in an old arsenal in Moorfields called "The Foundery" which he transformed into a "meeting house." From this point the history of the evolution of Methodism as a church may be summarized in 10 steps:

The *first step* in the evolution of the church was the formation of religious societies through which the Wesleys exercised their spiritual influence. These societies were in part imitated from the Moravians and in part were the continuation of societies related to the Church of England, being successors of those groups which sprang up in the last years of the Stuarts to compensate for the decay of Puritanism within the Anglican Church.

The *second step* was taken in 1739 when Wesley, to avoid an antinomian quietism growing among the Moravians in England, formally separated from the Moravians to establish a society of his own at the Foundery as mentioned above. This became the first society under the direct control of Wesley and the beginning of the Wesleyan Methodist Society.

The *third step* was taken in 1740 because the clergy excluded the Wesleys from their pulpits and repelled them and their converts from the Lord's Supper. The brothers therefore took the decisive step of administering the sacrament to their societies themselves in their own meeting rooms, both at Bristol and at Kingswood. The only link which now connected the administration of the sacrament to these societies with the Church of England was that the preachers who served the Lord's Supper were among its priests.

The *fourth step* was taken in 1741 when Wesley called out lay preachers to itinerate under his direction. To the societies founded and sustained with the aid of these preachers, who were absolutely under Wesley's personal control, the two brothers in their extensive journeys administered the sacraments as they were able. Despite Wesley's injunctions that his societies should generally keep to their parish churches, the societies wanted to have their own full Sunday services and to have the sacraments administered by their own preachers. The development of these preachers into ministers and of the societies into fully organized churches was the natural result of Wesley's designation of spiritual agents to carry on the work that was continually opening up before him.

The *fifth step* was taken in 1742 with the division of the societies into classes with leaders appointed as lay spiritual helpers and subpastors, and as stewards to take and give account of moneys received and expended.

The *sixth step* was by the Wesley Brothers in 1743, who published the *Rules of the United Societies* which have continued unaltered as the rules of Wesleyan Methodism. The Society was described as a "company of men having the form, and seeking the power of godliness, united in order to pray together, to receive the word of exhortation, and to watch over one another in love, that they may help each other to work out their salvation." The condition of membership in the societies was stated as a "desire to flee from the wrath to come and to be saved from their sins." The minimum customary contribution was a penny a week to "help the poor"; later the contributions were paid more generally toward "the support of the gospel."

The *seventh step* was taken in 1744 when Wesley held his first annual conference composed of preachers whom he personally selected. These early conferences were chiefly useful for the settlement of points of doctrine and discipline and for the examination and accreditation of fellow laborers. The aging of the brothers and the authority of the evolving church so far existing only as a personal authority of the two brothers exercised either directly or by their official delegates, moreover, led Wesley in 1784 to provide for the perpetuation of his work by a deed poll enacted by Parliament which vested in trustees for the use of "the people called Methodists" under the jurisdiction of the conference as to the appointment of ministers and preachers all the preaching places and trust property of the con-

nection. The legal conference was defined as 100 itinerant preachers named by Wesley with power given to this "legal hundred" to fill vacancies in their own numbers, to admit and expel preachers, and to station them from year to year. Indeed, no preacher was allowed to remain more than three years in one station. By the constitution of this conference Wesley consolidated his movement into a distinct religious organization with legally corporate character and large property holdings.

The *eighth step* was taken when Wesley began to ordain ministers. This step gave the societies a yet more definite character as a separate church, yet Wesley protested that his societies were not a church. They were only a "society," the "United Society," the society of the "People Called Methodists," the "Methodist Society." In fact Wesley held the members of his society to be members of the Church of England, except for professed Dissenters whom he defined in a letter to Charles as those "who for conscience sake refused to join in the services of the church or partake of the sacraments administered therein." He interpreted the "Church of England" to mean "all the believers in England, except Papists and Dissenters, who have the word of God and the sacraments administered among them."

By 1746 Wesley abandoned his ecclesiastical high-churchmanship and revolutionized his views on ecclesiastical organization by reading Lord Chancellor King's account of the primitive church. From this time on he consistently maintained that the "uninterrupted succession was a fable which no man ever did or could prove." Indeed he was convinced by Lord King's book that the office of bishop was originally one and the same with that of presbyter. From this position he drew the practical inference that he himself was a "Scriptural Episcopos" and that he had as much right as any primitive or missionary bishop to ordain ministers as his representatives and helpers to administer the sacraments. Despite this belief he held this right in abeyance for three fifths of a century until at length he was constrained to exercise it. In doing so he in effect led the way toward making his society a distinct and independent church.

The *ninth step* was taken in 1784 when the independence of the American colonies made necessary the organization of a separate Methodism for America. Wesley declared that the colonial Methodists should be "totally disintangled from both the state and the English hierarchy." By giving formal ordination and letters to Thomas Coke, former curate of South Petherton and presbyter of the Church of England, Wesley commissioned Coke to preside over the "Flock in America" as presbyter and superintendent. Coke in turn associated himself with Francis Asbury (1745–1816), a preacher in the Wesleyan Conference in London. Asbury had come to America in 1771 as a volunteer missionary to the 400 Methodists in America. Against Wesley's order issued immediately before the outbreak of the Revolutionary War, Asbury alone refused to return to England.

The *tenth step* was taken at the Christmas Conference convened in Balitmore, Maryland, on Dec. 24, 1784. Sixty preachers met with Coke, approved an organizational plan submitted by Wesley, accepted his liturgy and hymnal, adopted the Articles of Religion with the addition of a clause recognizing the civil government and with the inclusion of a prayer for the rulers of the United States. The conference elected Coke and Asbury to the episcopal office. Asbury, with the approval of the Conference, was ordained by Coke. Thus Episcopal Methodism began in America with bishops considered only as chief administrative officers among the presbyters whom they superintended.

At the time of John Wesley's death in 1791 Methodism in Great Britain, the Isle of Man, and the Channel Islands numbered 19 circuits, 227 preachers, and 57,562 members; in Ireland 29 circuits, 67 preachers, and 14,006 members; in the West Indies and British America 19 preachers and 5,300 members; and in the United States 43,265 members.

DIVISION AND REUNION

In America.—Methodism as a church became divided as a result of two wars and the philosophy of political independence which affected church organization. The American Revolution precipitated the first major cleavage along nationalistic lines. In the year that the battles at Lexington and Concord were fought, all the Methodist preachers except Asbury and Thomas Rankin left America. Indeed during the war a Methodist was classified as a Tory until he proved himself otherwise. Wesley, to make the position of the Methodists more difficult, declared: "We Methodists are no republicans and never intend to be." Following the Treaty of 1783, however, Wesley released the Methodists from their British connections and urged them "to stand fast in that liberty wherewith God has so strangely made them free." Methodism in the new union separated from British Methodism on nationalistic lines.

The first important division within the new Church in the United States led to the organization of the *Methodist Protestant Church.* The Methodist Protestant group insisted on the right of a layman to vote on any question in any church meeting and the administration of the church without bishops. "Having no traditional prejudices in favor of a divine right monarchy or a divine right hierarchy," they said, they took for their model "the church without a bishop and the state without a king." By insistence upon these two principles the Methodist Protestants sought to bring church government, as they said, into harmony with the Republic and to make it conform to the principles of the "Kingdom of God." The Methodist Protestants, being unable to work out their reform within the Methodist Episcopal Church, assembled 114 delegates at Baltimore on Nov. 2, 1830, to separate and found the Methodist Protestant Church.

The second important division in America occurred in 1844 when the *Methodist Episcopal Church, South,* separated from the Methodist Episcopal Church. On the northern side the division was considered to have resulted from the slavery issue; on the southern side it was considered merely to be a constitutional issue over the powers of the episcopacy. After years of discussion, negotiation, and litigation, the Cape May Commission, established in 1876 by joint membership and action of the Methodist Episcopal Church and the Methodist Episcopal Church, South, reached terms of amity according to which each body recognized the other as a legitimate branch of Methodism and laid the basis for a peace which moved steadily toward reunion. The Methodist Episcopal Church, the Methodist Epis-

copal Church, South, and the Methodist Protestant Church, by a Declaration of Union issued at Kansas City, Missouri, on May 10, 1939, came together again as a united church with more than eight million members under the name of *The Methodist Church,* retaining however permanently the names of the three constituent churches and authorizing these names forever to be carried in the Discipline.

The Methodist Church in America also took morphology along color lines. The *African Methodist Episcopal Zion Church* (489,244 members) was organized in 1796 out of the old John Street Methodist Episcopal Church in New York. The *African Methodist Episcopal Church* (868,735 members) was organized in Philadelphia in 1816 and extended throughout the South after the Civil War. The *Colored Methodist Episcopal Church* (381,000 members) was organized with the approval of the General Conference of the Methodist Episcopal Church, South, in 1870 to bring its colored membership, at the request of the colored members, into a separate ecclesiastical body. By provision of the constitution of The Methodist Church after its unification in 1939 the Negro membership is organized in what is known as the Central Jurisdiction, an administrative unit which includes all the Negro annual conferences, Negro mission conferences, and missions in the United States. The Central Jurisdiction is based on color rather than geography as is the case in the other administrative jurisdictions.

The *Yearbook of American Churches* (1947) records nineteen independent varieties of Methodism in the United States. Among these groups, totaling 1,871,718, of which number three major Negro bodies comprise 1,739,979 members, are the Reformed Methodists (1814), Primitive Methodist Church (1830), Wesleyan Methodist Connection in America (1843), Congregational Methodist Church (1852), Free Methodist Church of North America (1860), New Congregational Methodist Church (1881), Holiness Methodist Church (1900), Independent A.M.E. Zion Denomination (1907), and the Apostolic Methodist Church (1932).

In Great Britain.—Division in Great Britain began in 1797 when Alexander Kilham, expelled from the Wesleyan Conference for his violent zeal directed toward abolishing the distinction between ministers and laymen, founded the *New Connection.* Other divisions resulted in the organization of *Primitive Methodist, Bible Christians, Protestant Methodists,* the *Wesleyan Methodist Association,* and the *Wesleyan Reformers.* In 1857 the Protestant Methodists, the Wesleyan Methodist Association, and the Wesleyan Reformers formed a union as the *United Methodist Free Churches.* In 1907 these were incorporated with the Methodist New Connection and the Bible Christians as the *United Methodist Church.* In 1932 the Wesleyan Methodists, the Primitive Methodists, and the United Methodists merged into one church as the *United Conference of Methodist Churches.* One special separation deserves mention. In the 1860's William Booth withdrew from the ministry of the New Connection to organize the *Salvation Army* as an international quasi-military religious organization to bring religion and social service to the masses, finding opposition to his specialized ministry not to his liking in the Church in which he had been ordained.

In Canada.—The history of Methodist expansion in Canada parallels the opening and settlement of the Dominion itself. Spread oftener by laymen than by preachers, Methodism was introduced into Newfoundland by Laurence Coughlan in 1765. Yorkshire Methodists settling in Nova Scotia in response to a call for British colonists, United Empire Loyalists in New Brunswick, soldiers of General Wolfe's army in Quebec, the Heck family migration to Ontario, missionaries to upper Canada and the Indians, encouragement from the Hudson's Bay Company, and saddle bag itinerants pressing westward to the Pacific all contributed to the spread of Methodism across the new continent.

On June 10, 1925, *The Methodist Church,* formed in 1884 by the merger of four Methodist branches (The Methodist Church in Canada, the Methodist Episcopal Church in Canada, the Primitive Methodist Church in Canada, and the Bible Christian Church) united with the Congregational Churches of Canada, the Presbyterian Church in Canada, and the Local Union Churches in Western Canada to form *The United Church of Canada.* The Methodist Church was the only one of the three denominations entering the union to bring into the United Church all its local churches. Negotiations looking toward this union, begun in 1899, were completed by the enactment of necessary legislation by the Parliament of Canada in 1924 and by the legislatures of the various provinces from 1924 to 1926. In 1930 the Wesleyan Methodist Church of Bermuda joined with the United Church of Canada as a Presbytery of the Maritime Conference. The United Church is carrying on negotiations looking toward organic union with the British and African Methodist Episcopal Churches (colored) whereby the two bodies may merge with the United Church of Canada.

Congregational in polity, the basic organization of the United Church is much like that of The Methodist Church in the United States except that it has no bishops and no elected or appointed ecclesiastical hierarchy.

In 1948 The United Church of Canada had eleven conferences, 115 presbyteries, 3,215 ministers, 6,580 preaching places, 528,955 families, 780,234 members, 5,068 church schools with 491,925 members, 21 hospitals, and church property valued at $103,955,432. Overseas missions are carried on in six fields, namely West Africa, North, South, and West China, Central India, Japan, Korea, and Trinidad.

The basic literature of the United Church consists of the *Hymnary* (1930) containing the great hymns of the ecumenical church drawn largely from the Presbyterian, Congregational, Methodist, Anglican, and Moravian churches; the *Book of Common Prayer;* the *Statement of Faith;* the *Catechism;* and the *Manual* which contains the doctrinal standards, constitution, and laws for the government of the church. The official church paper is *The United Church Observer* (1939) the product of a merger of several smaller publications. The general officers of the United Church of Canada are located 299 Queen Street, West, Toronto 2 B.

Among the Germans.—The practical nature of Methodism was nowhere more obvious than in the mission of the Methodist Episcopal Church to the Germans. Concerned with effective ministry to the German immigrants swarming into the United States in the 19th century, Bishop

Joshua Soule on Aug. 19, 1835, in concluding the Ohio Annual Conference appointed Wilhelm Nast as "German Missionary." A seminary classmate of David Friedrich Strauss, Nast came to the United States to settle at West Point as librarian of the United States Military Academy. Hearing a sermon of Wilbur Fisk in the West Point Chapel, Nast came under the influence of the Methodists, finding "grace abundant to his needs." Nast began his preaching as a German missionary in Cincinnati, holding class meetings in the home of James Gamble, an Irish soap maker. Itinerating in areas settled by German immigrants, Nast established Methodist societies and organized his advances into German-language speaking conferences. By 1915 the German work in the United States was organized into ten annual conferences extending from ocean to ocean and from Canada to Mexico. The German work was carried on in 761 churches with 644 preachers caring for 60,270 members. Including the Methodists in Germany and German-speaking sections of Europe, the German Methodist movement grew to about 120,000 members and 1,200 preachers.

Episcopal Methodism was carried from the United States to Germany by Ludwig Sigmund Jacoby, a Jew converted in Cincinnati under the preaching of Nast. Jacoby married Amalie Therese Nuelsen, a devout Catholic converted in Cincinnati under the preaching of Peter Schmucker. Pastor and Frau Jacoby arrived in Bremen on Nov. 10, 1849. Working against prejudice and the legal status of the established church, the Methodists gained a permanent footing and developed on the continent in organic relationship with the Methodist Episcopal Church in the United States. In 1874 the Bethany Society with motherhouse in Frankfurt am Main began a deaconess work which was to become a major contribution to the Methodist Church.

The strains of World War I together with the assimilation of the Germans in language and custom led to the integration of the German Methodism into the English-speaking church. Liquidation of German Methodism was begun by an enabling act passed by the 1924 General Conference and completed with the disbanding of the East German Conference in 1943.

The principal journal of German Methodism was *Der Christliche Apologete,* established by Nast as editor in 1839, edited by him until 1892, until 1918 by his son Albert, and until 1936 by a Swiss scholar, August J. Bucher. *Der Christliche Apologete* celebrated its centennial in 1939 and then discontinued publication.

The statesman of German Methodism was Bishop John L. Nuelsen, elected to the episcopacy in 1908 and assigned to administer continental Methodism in 1912. "Our battle," said Bishop Nuelsen, "is against sin, the flesh, the devil, and his works."

The work in Germany continues under the Germany Central Conference with episcopal headquarters at Frankfurt am Main where the German Methodist Theological Seminary is located and under the Provisional Central Conference of Central and Southern Europe with episcopal headquarters in Geneva, Switzerland.

The traditions of German Methodists were bound together into the history of the Methodist Church by the heroic efforts of John A. Diekmann, who became president of Bethesda Institutions in Cincinnati in 1922.

The Methodists also developed strength among the Scandinavians, Chinese, Japanese, Italians, and Latin Americans in the United States. The Northern European Central Conference, administered from Stockholm, continues as a substantial overseas area of Methodist work.

PROTESTANT COOPERATION

The Methodists in the United States constitute the largest constituent body of the Federal Council of the Churches of Christ in America, a general Protestant federation organized at Philadelphia in 1908. The Methodists have also played a leading role in the organization of the World Council of Churches, established by constitution promulgated at Amsterdam, Holland, in 1948. The Methodist layman, John R. Mott, became the first honorary president of the Assembly and Bishop G. Bromley Oxnam, of the New York Area of the Methodist Church, president of the Federal Council of the Churches of Christ in America from 1944 to 1946, became one of the six World Council presidents.

DOCTRINE

Methodist theology expresses an eclectic evangelical Arminianism. Wesley explained his conception of doctrine in 53 sermons known as the four volume edition of 1787–1788 and in his *Explanatory Notes Upon the New Testament* (1755). To a generation which believed in heaven and hell as objective entities in the other world, to Englishmen advised by Calvinists that God had predestined every man, some to hell and some to heaven for eternity, Wesley offered the comforting assurance that any man seeking to be saved from his sins and desiring to live the Christian life could by an act of faith find God's grace abundant to his needs and could be born again. The sovereignty of God, according to the Methodist preaching, was so exercised as to be compatible with the freedom of man, divine grace originating, maintaining, and perfecting man as God's free gift. The sequence of Methodist spiritual psychology runs from original sin through repentance, justification by faith, the witness of the spirit defined as the consciousness of the divine favor through the atonement of Jesus Christ, and Christian perfection.

Methodists recognize the two sacraments as ordained by Christ to be baptism and the Supper of the Lord. To Methodists a sacrament is a certain sign of grace and of God's good will toward man by which God works invisibly in man to quicken, strengthen, and confirm man's faith in God. Baptism is both the mark of difference which distinguishes a Christian from others and a sign of regeneration and new birth. The Supper of the Lord is a sign of love that Christians ought to have among themselves one to another and a symbol of man's redemption by Christ's death. The visible Church of Christ to the Methodists is a congregation of faithful men in which the "pure word of God" is preached and the sacraments duly administered according to "Christ's ordinance." The local church is a society of persons who have professed the faith and have joined together in the fellowship of a Christian congregation in order to pray together, to receive the word of exhortation, and to watch over one another in love, that they may help each other to work out their salvation. Any confusion in the theological position of Methodism is explained by its pragmatic concern for practical rather than ecclesiastical detail.

POLITY

The organization of Methodism is divided into two general forms by British and American Methodism.

British Methodism.—During his life Wesley acted between conferences as patriarch and visitor with summary and supreme jurisdiction. By a letter produced after his death he begged the members of the Legal Hundred to assume no advantage over other preachers in any respect. Instead of appointing bishops, therefore, the preachers divided the country into districts with operating committees within these districts. Presently chairmen were elected for the whole conference each year.

American Methodism.—In the United States the organization of The Methodist Church is episcopal, with bishops serving as superintending presbyters rather than as prelatical or diocesan officers. The bishops, elected by jurisdictional conferences oversee the spiritual and temporal affairs of the church, preside in the General Jurisdictional, Central, and Annual conferences, annually appoint preachers, district superintendents, deaconesses, and connectional officers, and execute the policies and programs established by the General, Jurisdictional, and Annual conferences. The bishops are organized in three groups: a College of Bishops composed of all the bishops assigned to or elected by a Jurisdictional or Central conference; a Council of Bishops composed of all the bishops of all the jurisdictions and central conferences; and a Conference of Methodist Bishops composed of all the bishops elected by the General, Jurisdictional, and Central conferences, and bishops of affiliated autonomous Methodist Churches meeting each quadrennium immediately prior to the General Conference or on call of the Council of Bishops.

Bishops for purposes of residential and presidential supervision are assigned to convenient geographical areas by a jurisdictional conference upon the recommendation of a Committee on Episcopacy composed of ministerial and lay delegates.

Jurisdictions.—The United States is divided into six jurisdictions, namely the Northeastern, Southeastern, Central (Negro), North Central, South Central, and Western.

Conferences.—For effective action, the work of the Methodist Church is organized in a pattern of conferences. The quadrennial "General Conference" exercises supreme legislative and policy-making power for the entire church over all active connectional matters. The "Quadrennial Jurisdictional Conference" meets after the adjournment of the General Conference, elects bishops, and plans details for carrying out the program of the General Conference within the jurisdiction. Delegates to both the General and the Jurisdictional conferences, are elected by the Annual Conference. The *Annual Conference* is the *basic body in the church.* It is composed of all traveling preachers and lay members elected by each pastoral charge. District Conferences are informal administrative units of the Annual Conference corresponding to the geographical districts presided over by an administrative officer known as a district superintendent appointed by the bishop presiding over the Annual Conference. The "Quarterly Conference," presided over by the district superintendent, is the governing body of the pastoral charge. Central Conferences are administrative units for the work of the church outside the United States to promote evangelistic, educational, missionary, and benevolent interests and institutions. These bodies elect their own bishops.

Recognizing the need for national leadership, the Methodist Church provides for Affiliated Autonomous Churches defined as self-governing churches in whose establishment The Methodist Church has assisted and with which it is cooperating through its Board of Missions and Church Extension.

Administrative Agencies.—The Administrative Agencies of the Methodist Church are the Methodist Publishing House; the Board of Missions and Church Extension, composed of a Division of Foreign Missions, Division of Home Missions and Church Extension, Woman's Division of Christian Service, and Division of Education and Cultivation; Board of Education composed of a Division of Educational Institutions, University Senate, Commission on Ministerial Training, Division of the Local Church, and Editorial Division; Board of Temperance; Board of Lay Activities; Board of Hospitals and Homes; Board of Evangelism; Commission on World Peace; Commission on Public Information; and Commission on Chaplains.

The Methodists, never divorcing personal religion from its social application, have continually agitated for total abstinence and legal prohibition of the liquor industry, a just and durable peace, and have given some concern to the ethics of the programs created by industrial society.

STATISTICS

The official 1948 discipline gives the estimated membership of world Methodism as 13,281,000. Statistics for the United States, Territories, and Cuba, are: 40,321 preaching places, 21,603 pastoral charges, 5,343,446 persons enrolled in church schools; annual church school offerings $12,630,005; 1,442,421 members of Woman's Societies of Christian Service raising $16,024,061; annual expenditures of local churches, $164,138,457; local church property, less indebtedness, $1,475,530,795; 9 universities; 10 schools of theology; 69 colleges; 26 junior colleges; 10 secondary schools; 71 hospitals; 55 homes for the aged; 41 homes for children; and mission work carried on in 49 foreign countries in 125 different languages. Per capita giving for all purposes is reported in the 1947 *Yearbook of American Churches* as $18.33.

LITERATURE

The basic literature of the Methodist Church includes the *Discipline of the Methodist Church,* published quadrennially; *The Methodist Hymnal; The Christian Advocate,* weekly journal; and extensive periodical and instructional literature published by the administrative agencies of the church. The publishing interests of the church are organized in the Methodist Publishing House (founded in 1789 as the Methodist Book Concern), the profits of which are annually distributed through the annual conferences as pensions to retired preachers.

PAUL F. DOUGLASS,
President, The American University.

METHODIST PUBLISHING HOUSE, The, a company established in 1789 in Philadelphia as The Methodist Book Concern. It has branches in 14 cities and publishes thousands of books and pamphlets each year.

METHODIST YOUTH FELLOWSHIP, The. When the three Methodist bodies united in 1939, it was necessary to unify the youth work in the three churches. This union was completed in 1941 when the Methodist Youth Fellowship was launched. The name was chosen by a vote of the young people throughout the church. The details of organization were largely planned by youth groups, although the responsibilities for promoting the program lie with the Youth Department of the Board of Education of the Methodist Church. The Methodist Youth Fellowship includes all of the young people connected with the church school between the ages of 12 and 23 years, inclusive. This includes those attending the Sunday morning sessions of the church school, Sunday evening meetings such as Epworth League (q.v.), Christian Endeavor, and University of Life, or other youth groups within the church.

The national organization is known as the National Conference of the Methodist Youth Fellowship. Its membership is composed of presidents of annual conference youth organizations, the presidents of state or regional student organizations, representatives from the staff of the agencies working with youth in church, and selected young people designated by the conference.

The Methodist Youth Fellowship is organized in each annual conference of the Methodist Church and provision is made for district and subdistrict organization where desired. In the local church, the Methodist Youth Fellowship is divided into three departments: (1) intermediate (ages 12, 13, and 14); (2) senior (ages 15, 16, and 17); and (3) young people (ages 18 to 23). Intermediates do not participate in the program beyond the local church. Provision is made for two types of youth organization. Plan I provides for a unified plan with one set of officers serving for all functions within a given age range. Plan II provides for separate organization for morning and evening sessions or as many divisions as seem advisable for the local church.

The activities of the organization on each age level (conference, district, subdistrict, and local church) are carried on through four commissions: Commission on Worship and Evangelism; Commission on World Friendship; Commission on Community Service; and Commission on Recreation and Leisure. The National Conference of the Methodist Youth Fellowship is responsible for specific projects in the youth field and has its own secretary who is a co-operating member of the Youth Department and the Department of Student Work in the Board of Education of the Methodist Church.

METHODIUS, mĕ-thō′dĭ-ŭs, **Saint.** See CYRILLUS AND METHODIUS.

METHOW, mĕt′hou, river, in the north central part of the State of Washington. Rising in the Chelan National Forest, it flows southeasterly and merges with the Columbia River just east of the town of Pateros. The Methow drains the larger part of the western half of Okanogan County. The narrow valley to which the river gives its name has no large towns, and is given over principally to farms, orchards, and pasture lands. It is especially well known for its apple orchards which produce four excellent varieties of apple—Delicious, Winesap, Jonathan, and Rome Beauty. Owen Wister drew upon this locality for several of the characters and episodes in his novel, *The Virginian.*

METHUEN, mĕth′ū-ĭn, 3D BARON (PAUL SANFORD METHUEN), English general: b. Corsham Court, Wiltshire, England, Sept. 1, 1845; d. there, Oct. 30, 1932. He is descended from John Methuen who effected the treaty, named after him, between England and Portugal in 1703. He studied at Eton; entered the Scots Fusilier Guards in 1864; saw special service on the Gold Coast in 1873; received a medal for bravery in the Ashanti War in 1874; became attaché in Berlin (1878), assistant quartermaster general Home District (1881), and quartermaster general in the Egyptian War (1882). He was in command of the Home District from 1892 to 1897; and commanded a division in the unsuccessful attempt at the beginning of the South African War to relieve Kimberley. At Magersfontein (1899) he was defeated. With Lord Roberts he marched on Pretoria in May 1901. In March 1902 he was captured between Vryburg and Lichtenburg, but immediately released. His ill success in South Africa was attributed to the difficult circumstances, and he was placed over the Eastern Command after the Boer War. In 1907 he was commander in chief in South Africa, in 1909 governor of Natal, was created fieldmarshal in 1911; in 1915–1919 governor of Malta; and after 1920 governor of the Tower.

METHUEN, town, Massachusetts, in Essex County; altitude 105 feet; on the Spicket River; 28 miles northwest of Boston, on the Boston and Maine Railroad. Its industrial products are yarn, shoddy, worsted cloth, shoes, wooden heels, brooms and weaving equipment. The Nevins Memorial Hall and Library, and Methuen Memorial Music Hall are notable buildings.

First settlement of the site was made about 1642; it was included within the limits of Haverhill until 1725, when it was incorporated as a separate municipality. In 1917 it was chartered as a city, but in 1921 it returned to town government. It was named for Sir Paul Methuen, pre-Revolutionary official. Pop. (1940) 21,880; (1950) 24,477.

METHUEN TREATY, a commercial treaty between Great Britain and Portugal, signed in 1703 and annulled in 1835, dealing with the tariff on wines and wool, negotiated by John Methuen, the British ambassador.

METHUSELAH, mĕ-thū′zĕ-lä ("a man with a dart"?), Hebrew patriarch. The name appears in old manuscripts also as Mathusala

and Mathusale. It has been variously translated as "Man of God," "Man of the Javelin," "Man of Sin," "Man of Selah." Because Selah was a title of the god Sin, these other derivations are possible. He is remarkable as the oldest man mentioned in the Bible, his age being stated in Genesis 5:27 as 969 years. According to Hebrew chronology and to that of the Samaritan version (which, however, reduces his age to 720 years), he died in the year of the Flood; but the Septuagint calculation makes him die six years earlier. Few will be found who believe that a man ever attained such an age. The most rational conclusion is that the original writer had in mind a period different from the year of 365 days.

METHYL, měth'ĭl. The simplest and most common organic radical is known as methyl and has the formula CH_3. It will be readily seen that this corresponds to one molecule of methane, CH_4, from which one atom of hydrogen has been removed, and it would not be expected to be a stable substance. As will be pointed out later in the discussion of free radicals, it has only momentary and fugitive existence in organic reactions.

The term radical, while still in common use in the chemistry of carbon compounds, is not employed to any extent in discussing the chemistry of other elements. The term originally applied to any group of atoms present in a number of similar compounds which conferred certain specific chemical properties on all of them. Inorganic radicals were such groups as sulphate (SO_4), nitrate (NO_3), and ammonium (NH_4). With the development of the modern theory of ionization it was recognized that these groups existed, when compounds containing them were dissolved in liquids of high dielectric properties. Such radicals are known to possess electrical charges due to an excess or deficiency of one or more electrons, and are regarded as negative or positive ions.

Ionization is a much less common phenomenon in carbon chemistry, but in spite of the fact that only comparatively few organic radicals can exist longer than a fraction of a second, the idea of setting apart such groups and learning more about their influence in an entire organic molecule is still very useful and generally employed.

The hydrocarbon radicals are generally regarded as hydrocarbons from which an atom of hydrogen has been removed. Their names indicate their origin as: methyl, CH_3 from methane, CH_4; butyl, C_4H_9, from butane, C_4H_{10}. An exception is phenyl, C_6H_5, which bears a similar relation to benzene, C_6H_6. The name, however, is derived from phenol, C_6H_5OH.

As an example of the effect of different radicals on the properties of the same parent substance, the alkyl resorcinols may be cited. The resorcinols, in which R stands for any alkyl radical of the formula C_nH_{2n+1}, may be represented as $RC_6H_3(OH)_2$. Beginning with methyl and using those radicals with a single straight carbon chain, the antiseptic properties gradually increase with each additional carbon until the radical is hexyl, C_6H_{11}. Further increase in the length of chain is marked by a steady decrease in physiological activity.

For instructional purposes organic chemists very commonly think of many carbon compounds as being derived by the replacement of one or more hydrogen atoms by another atom or group of atoms. It is, of course, well known that relatively few carbon compounds are actually made in this way in spite of the recent rise in the use of petroleum hydrocarbons as chemical raw materials. Using the idea of hydrocarbons as a point of origin, a few substances may be considered as typical. The methyl group from methane is present in all of these substances: methyl chloride, CH_3Cl; methyl alcohol, CH_3OH; methyl cyanide, CH_3CN; methylamine, CH_3NH_2; and dimethyl ether, CH_3OCH_3.

In the middle of the past century, it was believed that the free methyl radical was produced when an iodine atom was removed from methyl iodide, CH_3I, by zinc. It was only when methods of determining molecular weights were developed that it was shown that the supposed methyl was in reality CH_3CH_3 or C_2H_6, ethane. So for many years the idea that free radicals were formed in chemical reactions and subsequently combined was an abstraction. In 1897 Prof. Moses Gomberg of the University of Michigan, in preparing hexaphenylethane, $(C_6H_5)_3C{-}C(C_6H_5)_3$, found that a free radical, triphenylmethyl, $(C_6H_5)_3C$, was formed when the saturated hydrocarbon was put into solution. Since that time a considerable number of free radicals have been made in which several ring structures in each molecule are involved.

A still more important development in the study of the mechanism of organic reactions has been in the field of unstable free radicals that are simpler than the stable free radicals heavily loaded with ring structures. Such studies deal with a series of relatively simple steps involving both free radicals and free atoms. Only the most fundamental concepts are given here.

As early as 1925 Prof. Hugh S. Taylor of Princeton suggested that free radicals might be involved in chain reactions such as the mercury photosensitized hydrogenation of ethylene. Active free radicals and atoms may be produced by heat, by the use of sensitizers, by photochemical effects, and by electrical methods. A common method of detecting and estimating free atoms and radicals is by their reactions with metallic mirrors previously deposited in glass tubes. The products of such reactions can be isolated as metallic alkyls. Other methods include the use of isotopes, paramagnetism, exchange reactions, and such physical determinations as rate of diffusion, heats of reactions, and optical effects. A typical thermal reaction involving a free radical is:

$$CH_3 + I \rightarrow CH_3I$$

METHYL ALCOHOL. See Alcohol and Methyl.

METHYLATED SPIRIT, is ethyl or grain alcohol to which has been added several per cent of methanol, methyl alcohol. While most methanol is now made synthetically, the product of destructive distillation of wood, or the common wood alcohol of commerce, it is preferred as a denaturant, being equally as toxic and possessing an unmistakable and unpleasant odor due to various impurities. The term methylated spirit is not now in common use, various grades of commercial alcohol being known as specially denatured and completely denatured and containing a number of different denaturants depending on industrial uses.

METHYLENE, Bichloride of, an organic compound of great value as an anæsthetic. It is a colorless fluid having an odor like that of chloroform, and is pleasant to inhale.

METHYLENE BLUE, an aniline dye a bluish crystalline powder having a bronze-like lustre. It is used in medicine, and in malaria is given as a substitute for quinine. See DYES.

METIS, mē'tis, *in ancient mythology,* the first wife of Jupiter, whom he was said to have devoured, after which Minerva (q.v.) was formed within his head.

METLAHKATLA, mĕt-lä-kä'tlä, or **METLAHKATLAH,** the native name of the oldest and most successful mission among the Indians of British Columbia, founded in 1857, by William Duncan, an English missionary, who developed a model community from a tribe of the lowest cannibals. A government school was opened there in 1913. Consult Arctander, K. J., 'Apostle of Alaska' (New York 1909).

METONIC CYCLE, a period of 19 solar years, after which the new and full moon fall on the same days of the year as they did 19 years before. This cycle was the discovery of Meton, a celebrated Athenian mathematician, 432 B.C. The Metonic cycle contained 6,940 days, which exceeds the true length of 19 solar years by 9½ hours nearly. On the other hand, it exceeds the length of 235 lunations, or synodic revolutions of the moon, by 7½ hours only. In the ecclesiastical calendar the number of the year in the cycle is called the golden number (q.v.). The cycle is supposed to commence with the year in which the new moon falls on the 1st of January.

METRE, mē'tėr, the unit of length in France,=39.37079 English inches, roughly one yard 3 1/3 inches. The metre was intended to be the ten-millionth part of the quadrant of a meridian of the earth. The *centimeter,* the one-hundredth part of a metre or nearly 4/10ths of an inch, possesses more advantages in physics as a unit of length; it is also found very convenient for many purposes for which the English yard is employed. See METRIC SYSTEM; WEIGHTS AND MEASURES.

In music, the equalization of time in the division of a composition. The measure (q.v.) is the smallest element in metre; two measures make a *section,* two sections make a *phrase* and two phrases make a *period.* See MUSIC.

In poetry, that measure of verse that determines the rhythm. It is commonly divided into feet and lines; a series of feet is a colon. See POETRY.

METRIC SYSTEM, The. In the latter half of the 17th century, the French astronomer, Jean Picard (1671), and the Dutch physicist, Christian Huyghens (1673), proposed as a standard unit of length that of a seconds pendulum at sea-level on the 45th degree of latitude. This is only about six millimeters shorter than the meter now in use. Some years earlier, Sir Christopher Wren had advocated that a half-seconds' pendulum should be chosen as such a unit; this would have approximated one-half the length commonly given to the ancient cubit. In 1670 the French mathematician, Abbé Gabriel Mouton, had suggested as a length unit one minute of the earth's circumference, what is now in use as a geographical mile, and he had divided and subdivided this decimally, giving a good Latin terminology for the various divisions and multiples. However, more than a century was to elapse before, under the inspiring influence of the spirit of innovation born of the French Revolution and its precursor, the American War of Independence, a new, scientific and logical system of weights and measures was created, one which has already replaced the old and illogical systems in a great part of the world and is probably destined to become, before many years shall have passed, the universal system. In view of the opposition to any change in this direction still shown by many to-day in England and the United States, it is a strange coincidence that in the very year (1790) when the first steps leading to the establishment of the metric system were taken in France, a new system of weights and measures was offered by John Miller to the British House of Commons, and also by Thomas Jefferson, the Secretary of State, to the House of Representatives of the United States. Jefferson's report formulated a decimal division of the various units. A still closer approximation to the metric system was present in that proposed by the inventor, James Watt, who selected as the unit of mass a definite volume of water, and provided for a simple interrelation of the units of length, area, volume and mass; he communicated this to Talleyrand.

As has been stated, it was in 1790 that the project for a new system of weights and measures was taken up by the French National Assembly. In March of that year, Talleyrand published a proposition to this effect, which he and Prieur des Vernois submitted to the Assembly. That body after referring the project to the Committee on Agriculture for preliminary consideration took it up on 8 May 1790 and on 22 August, a decree, sanctioned by Louis XVI, provided for the establishment of a new system, invited other nations to participate in the project and entrusted to the Académie des Sciences the task of determining on the unit to be employed as a standard. Some representatives from Spain, Italy, Denmark, the Netherlands and Switzerland took part in the discussion of the plan. The Académie des Sciences, in accord with the provisions of the decree, appointed a committee composed of the scientists Borda, Lagrange, Lavoisier, Tillet and Condorcet, and on 27 Oct. 1790, this committee submitted its report to the Assembly. To secure additional data, a second committee was appointed, in which Laplace and Monge were substituted for Lavoisier and Tillet. This second committee, in its report of 19 March 1791, recommended the adoption of the one ten-millionth part of the quadrant of the terrestrial meridian as the standard unit of length. The Assembly accepted this suggestion, and on 26 March 1791 appointed five commissions, each charged with some department of the arduous task. It was decided to make, as an exact basis of calculation, a measurement of an arc of 10 degrees on the meridian of Paris. The composition and attributions of the commissions were as follows:

1. Cassini, Méchain, Legendre; to measure the difference of latitude between Dunkirk and Barcelona, and to compute the triangles.

2. Monge and Meusnier; to compute the bases.

3. Borda and Coulomb; for the observation of the pendulum.

4. Lavoisier and Haüy; for researches as to the weight of distilled water.

5. Tillet, Brisson and Vandermonde; for comparison of ancient measures.

On 1 Aug. 1793, the Convention passed a decree, on the proposition of Arbogast, to the effect that the use of the new system should be declared obligatory at the end of the year. In this decree the nomenclature of the system was determined. Unavoidable delays in the measurement of the arc necessitated some successive modifications, and it was not until the 11th Ventôse, An III (1 March 1795) that an approximately definite report was sent in, to be followed by the decree of 18th Germinal, An III (7 April 1795), which finally established the different parts of the metric system. Lavoisier and Haüy were assisted by Le Fevre–Gireau and Fabbroni in determining the exact weight of a definite volume of water.

The decree of 7 April ordered the continuation of the operations for the exact determination of the units, and to this end provided for 12 commissions to be named by the Committee of Public Instruction. The members chosen were: Berthollet, Borda, Brisson, Coulomb, Delambre, Haüy, Lagrange, Laplace, Méchain, Monge, Prony and Vandermonde. On 16 July 1795, Borda and Brisson presented their report of the verification of the meter, but the measurement of the meridian arc, begun by Delambre and Méchain, 25 June 1792, could only be terminated in 1799. It is interesting to learn that, some years later, the work was continued in the Balearic Islands by Biot and Arago.

As a first step in the legislative enforcement of the system, a decree of 23 Sept. 1795 (1st Vendémiaire, An IV) had provided that its use should be obligatory in the commune of Paris, and in the 'Constitution de l'An IV (1795–96)' its principle was formally recognized. On 16 Oct. 1798 (25th Vendémiaire, An VII), there assembled in Paris a body composed of the delegates of 10 independent nations, designated to establish finally the fundamental units. The report, made in the following year by Van Swinden, of the Batavian Republic, gave the conclusions arrived at, and determined the length of the meter as 443 296/1000 lines of the old "Toise de Pérou," the latter being approximately equivalent to 6.3944 English feet. This report was adopted by the Convention 22 June 1799 (4th Messidor, An VII), and the prototypes in platinum of the meter and kilogram were presented by the Institute. They were immediately deposited in the Palais des Archives of Paris, copies being placed in the Conservatoire des Arts et Métiers, and in the Observatory of Paris, while iron meters were consigned to several foreign countries, including the United States.

It is well worthy of note, in view of the eventual absolute success of the metric system, that at first its progress was slow. For quite a time the people continued to cling to the old measures, and this led, under the First Empire to the promulgation of a ministerial edict, dated 28 March 1812, authorizing the employment of "transitory measures"; among which were the use of a *toise* (fathom) of 2 meters (the actual length of the old *toise* was 1.949 meters), of an *aune* (ell) of 1.20 meters, of a *boisseau* (bushel) of 12.5 liters, etc. It was not until the monarchy of Louis Philippe that absolutely final and decisive action was taken in the matter. The Marquis de Laplace presented to the Chamber a report, upon which was based the law of 4 July 1837, according to the terms of which "all weights and measures except those established by the laws of 18th Germinal, An III and of 19th Frimaire, An VIII (7 April 1795 and 10 Dec. 1799)" should be prohibited after 1 Jan. 1840. Belgium, Holland and Greece were the first countries to adopt the metric system, and before the end of the 19th century, it had become the standard with 40 nations, and had attained world-wide use in science.

Nearly a score of years before the passage of the French law just mentioned, the movement for the adoption of the system in the United States had already found able advocates, one of the most notable being John Quincy Adams, who in a report made to the Senate, on 22 Feb. 1821, proposed that an international conference should be held to study the merits of the metric system and to provide for co-operation with France tending toward its universal adoption. In the same year two metric standards, made of platinum, were sent to the United States by Albert Gallatin (1761–1849), then Minister to France. They were both authenticated by a certificate from the great physicist Arago, stating of the kilogram that it differed less than 1 milligram from the original "kilogramme des Archives." In form it is a cylinder with flat bases, the edges slightly rounded. Height and diameter are nearly equal, approximately 39.5 millimeters each. The only distinguishing mark is a faint lathe or tool mark of a point within a circle. The square mahogany box in which it was placed bore the following words engraved on a silver plate attached to the cover: "Kilogramme comparé pour son Poids a l'Étalon Protype des Archives de France, et verifié par M. Arago. Fortin fecit." Despite the assertion that its variation from the standard was but 1 milligram, it was found, when compared in 1879 with the British platinum kilogram, to be 4.25 milligrams light, and this finding was confirmed in 1884, when it was taken to the International Bureau of Weights and Measures at Sèvres, and compared with two auxiliary kilograms known to have the same values as the kilogram of the Archives. This final determination gave the error as —4.63 milligrams. The intrinsic worth of this platinum kilogram to-day, with the metal quoted at $105 per ounce Troy, would be $3,375, while at the time it was made the value would hardly have exceeded $300.

Older than the Arago kilogram is the "committee meter," as it has been called, which was given to Mr. F. R. Hassler, later superintendent of the Coast Survey, by J. F. Tralle, the deputy from the Helvetic Republic in the committee charged with providing for the production of the metric standards in 1799. It was brought by Mr. Hassler to the United States in 1805, and was a short time later donated by him to the Philosophical Society of Philadelphia. Not long afterward, when Mr. Hassler took

up the Coast Survey work, the society placed this standard at his disposal, and until 1890 it served as the standard for the determinations made by the survey. This meter is made of iron, and is marked with the stamp of the committee, which was a small ellipse, having three quadrants shaded, the remaining one bearing the figures 10,000,000, that of the number of meters in a quadrant of the earth's meridian.

Almost a half century elapsed after the proposal of a metric conference by John Quincy Adams before this project was realized. On 1 Sept. 1869, a decree of Napoleon III summoned an international conference to provide for the production of new and absolutely exact metric standards of mass and length. Fifteen nations responded to this invitation, and the delegates assembled in Paris, 8 Aug. 1870. In spite of the fearful disasters of the French armies and the consequent rapid invasion of French territory by the Germans, five meetings were held before the conference was forced to disband. The following were the 15 countries accepting the invitation of the French government to send representatives to this first Paris conference, of August 1870: Austria, Ecuador, France, Great Britain, Greece, Italy, Norway, Peru, Portugal, Russia, Spain, Switzerland, Turkey, United States, Colombia.

The project was not abandoned, however, and a second conference was called two years later, under the Third Republic, and representatives of 30 nations assembled in Paris on 24 Sept. 1872, remaining in session until 12 October of that year. Their deliberations resulted in the adoption of 40 resolutions bearing on the construction of the new standards; of these 21 especially applied to the meter and 12 to the kilogram, the remainder referring to various details of the plan to be pursued, and to the precautions to be taken for the preservation of the standards when produced, as well as for the maintenance of their invariability. A most important point was the exact determination of the alloy to be employed, and the eventual decision was that it should be one of 90 per cent platinum and 10 per cent iridium, a tolerance of 2 per cent in excess or deficiency being permitted. This alloy possessed at once a high degree of hardness and of resistance to chemical action, and also was susceptible of receiving an exceedingly fine finish. A main share in the task of ensuring the production of a thoroughly satisfactory amalgamation of the metals was entrusted to the chemist, Henri Sainte-Claire Deville. The first ingot made had a weight of 238 kilograms and is commonly known as the "alloy of 1874," from the year in which it was produced. This alloy, however, did not meet with the approval of the commission, although several standards were made out of it to test its qualities. It was now determined to have recourse to the skill and experience of the great London firm of platinum refiners, Messrs. Johnson, Matthey and Company, and as a result of patient effort they were finally able to offer a casting which was found by the chemists of the International Commission, and by those of the French section, to exceed the requirments; from it were made 31 prototype meters and 40 kilogram weights. The meters were sent, early in 1887, to the International Bureau to be compared with the "mètre des Archives" and also with one another. By 1889 this task had been accomplished, and on 26 September of that year the work of the International Committee received the approval of a general conference assembled at Paris. The meter and the kilogram found to be in closest agreement with the meter and kilogram of the Archives were denominated the "International Meter," and the "International Kilogram," and were deposited at the International Bureau of Weights and Measures, in a vault provided with three separate locks, the keys to which are in the possession, respectively, of the Custodian of the Archives of France, the president of the International Committee and the director of the International Bureau. This vault must not be opened oftener than once in a year, and in the presence of the three officers to whom the keys have been confided. To each of the contributing countries were given two of each of the new standards, which were all accompanied by attested certificates of comparison, two hard glass thermometers, each of which had a table of corrections in terms referring to the hydrogen scale, and a piece of the alloy cut from the end of the bar and destined to be used in testing the coefficient of expansion; each kilogram had a rock-crystal bedplate and other requisites for its safe conveyance. The meters allotted to the United States, Nos. 21 and 27, bore corrections of +2.5 microns and —1.6 microns, respectively; the probable error of the determinations being estimated, as a result of 784 individual comparisons, at less than 0.2 microns. The two kilograms assigned were numbered 4 and 20, and had corrections in weight of —0.075 and 0.039 milligrams, and in volume of 46.418 and 46.402 milliliters, respectively. Here from 1,092 individual weighings the error of the determination is less than 0.002 milligrams. Meter No. 27 and Kilogram No. 20 were carefully packed and brought to this country under seal by George Davidson of the Coast and Geodetic Survey. On 2 Jan. 1890, President Harrison received them at the Executive Mansion. The seals were broken in his presence, and he gave a certificate to the effect that they had been received in good condition, and that he was fully persuaded they were the standards to which the report referred. The other kilogram and meter were received in July 1890, and were deposited in the Office of Weights and Measures where the meter and kilogram recognized by the President as national standards had already been placed. By a decision made by the superintendent of weights and measures, on 5 April 1893, and approved by the Secretary of the Treasury, the international meter and kilogram were made the fundamental standards of length and mass in the United States, this applying to the customary weights and measures as well as to those based on the metric units. The standards passed under the control of the Bureau of Standards on its establishment 1 July 1901, pursuant to the provisions of the act of 3 March 1901.

The International Prototype Meter is an irido-platinum bar, 102 centimeters in length. Three lines are engraved near each end of the bar; they are from six to eight microns wide, and about one-half millimeter apart, and the meter is defined as the distance between the middle line of each group, when the temperature of the bar is at 0° C. The lines used to define

the meter and its subdivisions were traced at the Conservatoire des Arts et Métiers in Paris.

While the preliminary work for the production of the new standards was in progress, in March 1875, another international conference was called by the French government, in which France, the United States and 15 other nations out of the 19 represented signed a convention on 20 May 1875, providing for the establishment and support of a permanent International Bureau of Weights and Measures, the management and control of which should be in the hands of an international committee having 14 members, each from a different country. As a site for this bureau, the French government assigned a piece of ground at Sèvres, in the Park of Saint Cloud, declaring it to be neutral territory. It was agreed that the expenses of the bureau were to be borne by contributions paid by the contracting governments, the amount being proportionate both to the population of the country and the extent to which the metric system was used there.

The routine work of the bureau is performed under the supervision of a body termed the International Committee of Weights and Measures. This is in turn subject to the control of a general conference to which all the contracting governments send delegates, and which is to meet at least once every six years. This conference is charged with all questions regarding the measures to be taken to spread the use of the metric system in the countries which have not yet adopted it, and it is also called upon to pass definitely upon any new fundamental determinations that may be proposed.

The Advantages of the Metric System and its Proposed Adoption by the United States and Great Britain.— The initial difficulty and expense incident to a substitution of the metric system for that now in use in the United States and Great Britain have been much exaggerated by many writers on the subject. There would be no necessity for absolutely replacing the machinery appliances now in use; all that would be needed in the great majority of cases would be to re-mark them in accordance with the metric scale, and to adjust their operations in accord with metric requirements. It has indeed been truly said that the only machines that would altogether lose their usefulness would be those for making the old measures. It need never be necessary to change the present lathes, drills, shapers, etc., since there would be no necessity for the manufactured objects to have a particular metric size; all that would be needed would be to have them marked and listed in the metric designations of their actual size. It should be borne in mind, in this connection, that at present the sizes of parts are seldom exact unit sizes, since they are not made to conform to an arithmetical rule but to the exigencies of their practical mechanical use.

The metric system finds an earnest advocate in Hon. William C. Redfield, Secretary of the Department of Commerce. In an address at the Fifth Annual Meeting of the Chambers of Commerce of the United States, in Washington, on 2 Feb. 1917, he said of our present system of weights and measures that it «stands as a bar across that path to foreign trade which it is necessary that we should tread.» In another address, made before the Philadelphia Chamber of Commerce, 10 Jan. 1917, he noted that it required four pages of an official publication to describe the various kinds of bushels that exist in America, and that the Philadelphia mint buys all its supplies and common metals by one kind of weights and measures, its precious metals by another, and does all its laboratory work by a third, this latter being, of course, the metric system. As at least a step in the right direction, he cites the frequent use in drawings of a decimal division of feet and inches.

As to the best means of generalizing the use of the metric system in the United States, Dr. Samuel W. Stratton, director of the Bureau of Standards, writes: «Commerce, technology, and science have, on account of their international character, availed themselves of the advantages of the metric system more than manufacturing, which is local, and, unlike exporting, not in direct touch with world markets. Hence science and commerce with their world-wide outlook should be the advisers of industry, and their conclusion is that the first principle is to supply what the customer needs, and that international business requires international weights and measures.»

As to one of the great merits of the system, we have the following emphatic opinion from the late Lord Kelvin (William Thompson, 1824–1907): «I believe I am not overstating the truth when I say that half the time occupied by clerks and draughtsmen in engineers' and surveyors' offices — I am sure at least one-half of it — is work entailed upon them by the inconvenience of the present farrago of weights and measures. The introduction of the French Metrical System will produce an enormous saving in business offices of all kinds — engineering, commercial, and retail shops.»

The Rt. Hon. Arthur J. Balfour, replying in 1895 to a deputation advocating the introduction of the system in England, used the following words: «Upon the merits of the case I think there can be no doubt whatever that the judgment of the whole civilized world, not excluding countries which still adhere to the antiquated systems under which we suffer, has long decided that the metric system is the only rational system.»

As a step in the direction of the metric system, the decimalization of the coinage has found some favor in England recently, the present florin (a two-shilling piece) being proposed as a new monetary unit since it is exactly one-tenth of a pound sterling. As the British farthing is one ninety-sixth of a florin, an exceedingly trifling reduction of its value would make of it a «cent» representing the one-hundredth part of the florin, and worth only a very small fraction less than one-half of the United States or Canadian cent. Another idea has been to add ten-pence to the value of the pound, which would then contain 250 pence or 1,000 farthings of unchanged value. A new florin, as the tenth of this new pound, would then be worth 100 farthings. It is interesting to note that the proposition to decimalize the British coinage by making the florin, the tenth part of a pound sterling or sovereign, a money of account, and sub-dividing it into hundredths, has for several years been essentially introduced in Peru, where

TABLE OF THE METRIC SYSTEM AND EQUIVALENTS

	Correct English spelling		Standard abbreviations
Length	10 millimeters	= 1 centimeter	10 mm = 1 cm
	100 centimeters	= 1 meter	100 cm = 1 m
	1000 meters	= 1 kilometer	1000 m = 1 km
Capacity	1000 milliliters	= 1 liter	1000 ml = 1 l
Weight	1000 milligrams	= 1 gram	1000 mg = 1 g
	1000 grams	= 1 kilogram	1000 g = 1 kg
	1000 kilograms	= 1 metric ton	1000 kg = 1 t

LENGTH

1 centimeter	= 0.3937 inch	1 inch	= 2.5400 centimeters
1 meter	= 3.2808 feet	1 foot	= 0.3048 meters
1 meter	= 1.0936 yards	1 yard	= 0.9144 meters
1 kilometer	= 0.6214 statute mile	1 statute mile	= 1.6093 kilometers
1 kilometer	= 0.5396 nautical mile	1 nautical mile	= 1.8532 kilometers

CAPACITY

1 milliliter	= 0.0610 cubic inch	1 cubic inch	= 16.3867 milliliters
1 milliliter	= 0.2705 U. S. fluid drachm	1 U. S. fluid drachm	= 3.6966 milliliters
1 milliliter	= 0.0338 U. S. fluid ounce	1 U. S. fluid ounce	= 29.5729 milliliters
1 liter	= 1.0567 U. S. liquid quarts	1 U. S. liquid quart	= 0.9463 liter
1 liter	= 0.9081 U. S. dry quart	1 U. S. dry quart	= 1.1012 liters
1 liter	= 0.2642 U. S. gallon	1 U. S. gallon	= 3.7853 liters
1 milliliter	= 0.2816 British fluid drachm	1 British fluid drachm	= 3.5515 milliliters
1 milliliter	= 0.0352 British fluid ounce	1 British fluid ounce	= 28.4123 milliliters
1 liter	= 0.8799 British liquid quart	1 British liquid quart	= 1.1365 liters
1 liter	= 0.2200 British imperial gallon	1 British imperial gallon	= 4.5460 liters

MASS OR WEIGHT

1 gram	= 15.4324 grains	1 grain	= 0.0648 gram
1 gram	= 0.6430 pennyweight	1 pennyweight	= 1.5552 grams
1 gram	= 0.7716 apothecaries' scruple	1 apothecaries' scruple	= 1.2960 grams
1 gram	= 0.2572 apothecaries' drachm	1 apothecaries' drachm	= 3.8879 grams
1 gram	= 0.0353 avoirdupois ounce	1 avoirdupois ounce	= 28.3495 grams
1 gram	= 0.0322 troy ounce	1 troy ounce	= 31.1035 grams
1 kilogram	= 2.2046 avoirdupois-pounds	1 avoirdupois pound	= 0.4536 kilogram
1 kilogram	= 2.6792 troy pounds	1 troy pound	= 0.3732 kilogram
1 metric ton (1000 kilograms)	= 0.9842 long tons (2240 lbs.)	1 long ton	= 1.0160 metric tons (1000 kilograms)
1 metric ton	= 1.1023 short tons (2000 lbs.)	1 short ton	= 0.9072 metric ton

the gold *libra,* coined as an exact equivalent of the British pound sterling, is divided into 10 silver *soles,* the sol thus being worth exactly $0.48665, or the same as the British florin. The sol is in turn divided into 100 *centavos* worth 0.48665 cent of our money.

The equivalents given in this article are based upon the following fundamental equivalents:

39.370000 United States inches	= 1 meter
39.370113 British inches	= 1 meter
0.2641776 United States gallon	= 1 liter
0.2199753 British Imperial gallon	= 1 liter
1 United States avoirdupois pound	= 0.4535924277 kilogram
1 British avoirdupois pound	= 0.4535924300 kilogram

A quantity can usually be expressed as a whole number if the proper metric weight or measure is selected. Even when a fraction is needed to express the metric equivalent of another weight or measure, one or two figures to the right of the decimal point generally give sufficient accuracy. Equivalents such as those in the tables here given are intended to be used only to the required degree of accuracy. For example, four inches is equal to about 10 centimeters; if greater accuracy is desired 10.2 centimeters or 102 millimeters may be taken.

GEORGE F. KUNZ.

METROPOLIS, Ill., city and Massac County seat; altitude 329 feet; on the Ohio River; 15 miles northwest of Paducah, Ky.; on the Burlington; Illinois Central; and Paducah and Illinois railroads; has large line service on the river. Here crates, baskets, tool handles, and railroad ties are made; also underwear, gloves, and furniture. The city has a Carnegie library, a hospital, and a courthouse. Nearby, in 1757, Fort Massac was built by the French; it was destroyed by the Cherokee Indians; its site was occupied by the British from 1765 to 1778; and the fort was rebuilt by "Mad Anthony" Wayne (q.v.) in 1794. A neighboring settlement became the city of Massac; between it and the fort was Metropolis City, which in 1843 became county seat. The two cities were merged under the present name in 1892. In 1908 the site of the fort was designated as a state park. It was here that George Rogers Clark (q.v.) crossed the Ohio on his way into the Northwest Territory; a statue of him stands in the park. Pop. (1940) 6,287; (1950) 6,093.

METROPOLITAN, the Greek name of an archbishop, whose see is the chief place or metropolis of a province. The metropolitan is above the bishop, but below the patriarch. The title of patriarch, however, is in use only in the Eastern churches. In Russia, the metropolitan is at the head of the hierarchy. In the Roman Catholic Church an archbishop may bear this title even though he does not have a metropolis as a see, thus the archbishop of Westminster is styled metropolitan.

METROPOLITAN MUSEUM OF ART, The, was founded in 1870. The present building in Central Park opened to the public ten years later. Its collections, the most extensive in the Western Hemisphere, cover a period of 5,000 years, representing the cultures of the ancient world and the Near and Far East as well as the arts of Europe and America.

Among the collections are the paintings, which include oils, pastels, water colors, miniatures and drawings. There are over 5,000 examples, among which are the works of Italian, Spanish, Dutch, Flemish, German, French, English and American artists.

Special collections include: the Benjamin Altman Collection (notable for Dutch paintings,

Renaissance decorative arts, and Oriental rugs and ceramics); the Theodore M. Davis Collection (notable for Italian paintings, Egyptian antiquities and European and Oriental decorative arts); the Michael Friedsam Collection (notable for early French and Netherlandish paintings and European and Oriental decorative arts); the H. O. Havemeyer Collection (notable for 19th century French paintings, Oriental paintings and decorative arts and prints); the George Blumenthal Collection (notable for paintings and decorative arts of the Middle Ages and the Renaissance); the Jules S. Bache Collection, which includes masterpieces of all the European schools of painting.

The collection of prints consists of woodcuts, engravings, etchings and lithographs dating from 1450 to the present.

The Egyptian Wing presents a vivid chronological picture of a highly-developed civilization. Outstanding in the display is a mastabeh tomb erected about 4,400 years ago for a Memphite dignitary named Pery-neb, rebuilt in its original form. The arts of Greece and Rome are well represented. Notable are a Greek statue, the best preserved of the early Attic Kouroi, and a bronze statuette of a horse from the 5th century B.C.

The collection of ancient art of Mesopotamia, Persia, Palestine, and Syria was augmented through substantial purchases made in 1947 and is represented by sculpture, metalwork, and pottery. Notable examples of ancient Assyrian art are a colossal winged bull and winged lion and a number of reliefs, the gifts of John D. Rockefeller, Jr., and of J. Pierpont Morgan.

The collections of Near Eastern art from Egypt, Turkey, Syria, Iraq, Iran, and India are highlighted by outstanding Oriental carpets, Arabic glass, Islamic pottery and metalwork inlaid with gold and silver. A number of Syrian mosque lamps and other pieces of enameled glass of the 13th and 14th centuries are among the rarest and most precious objects.

The collection of Far Eastern art is notable for a fine selection of Chinese sculpture, which includes superb pieces ranging in date from the late Chou dynasty (about 1050–249 B.C.) to the Ch'ing (1644–1912). Other oustanding phases of the collections are the early Chinese potteries, the later decorated porcelains, the early bronzes and the extensive group of paintings.

The collections of medieval art in the Metropolitan Museum together with those at The Cloisters form the most important assemblage of medieval art in America. Collecting toward the turn of the century by the late J. Pierpont Morgan and subsequent gifts to the Museum by his son, J. P. Morgan, brought to the Museum world-famous groups of Early Christian, Byzantine, Romanesque and Gothic objects.

The decorative arts of the Renaissance include numerous outstanding objects from the well-known Morgan, Altman, Havemeyer, Friedsam, Blumenthal, and Wentworth collections. Notable are the intarsia room from the Ducal Palace at Gubbio, the sculpture, the majolica and the goldsmith's work including the famed Cellini cup in the Altman Collection. French decorative arts of the 17th and 18th centuries are well represented as are the decorative arts of England from Elizabethan times through the 18th century.

The collection of musical instruments of all nations with some 4,400 objects, is the most comprehensive assemblage of this kind in the world. It includes prehistoric instruments as well as those of Europe, Asia, Africa, Oceanica and America. Reconstruction work, still in progress, has brought many instruments back into playing condition.

The collections of Arms and Armor—consisting of armor, weapons, horse equipment and other war gear from both Europe and the Orient and dating mainly from 1400–1800—ranks with European national collections in scope and quality. Signed works by the best-known artist-armorers of Augsburg, Nürnberg, and Milan and over 450 pieces with historical associations are included.

The American Wing is devoted to American decorative arts from the 17th through the first quarter of the 19th century. In rooms, most of them reconstructed with original woodwork, there have been assembled furniture, metalwork, ceramics, glass, prints and paintings to present the characteristic background of our ancestors.

The collection of the Costume Institute (formerly the Museum of Costume Art, at 18 East 50th Street) includes some 10,000 items of costume and accessories ranging from the 17th to the 20th centuries and a library of reference materials—periodicals, costume histories, old costume plates, patterns, sketches of Paris openings, etc.

Study-storages of costume, millinery, shoes and other accessories; specially-equipped designer workrooms where designers may work in privacy, a classroom and library facilities are available to Costume Institute members. Changing special exhibitions of historic and regional costumes are open to the public.

The Cloisters.—A branch of The Metropolitan Museum of Art, devoted to European medieval art is The Cloisters in Fort Tryon Park, New York.

METROPOLITAN OPERA ASSOCIATION, INC., an organization known as such since 1932, producing opera and music drama at the Metropolitan Opera House, New York City. Previous to 1932, the organization was known as the Metropolitan Opera Company, a term which had already been applied in the East to a succession of organizations which, under various types of management, had functioned there since 1883, when the theater was built. By the Metropolitan Opera Association, Inc., is meant, accordingly, the organization which has been regularly producing lyrical performances at the Metropolitan Opera House since 1932; however, the group of singers, instrumentalists, and other artists and technicians participating directly in production, including specifically all members who accompany the troupe on tour, have continued to be referred to loosely as the Metropolitan Opera Company, as distinguished from the association. The Metropolitan Opera and Real Estate Company, a corporation formed in 1892 to represent the interests of certain boxholders, had emerged the following year as owner of the building itself, and had thereafter leased the property to each successive producing agency, reserving for its stockholders, in lieu of rental, the use of the parterre boxes for all subscription performances. This corporation was dissolved in 1940, the Metropolitan Opera Association having raised through public subscription the sum of $1,057,000, from

166,000 donors, which enabled it to obtain possession of the opera house.

When the theater was completed in 1883, Henry E. Abbey, though appointed manager by a board of directors, initiated the enterprise as his own venture, and incurred a personal deficit during the first season estimated at from $300,000 to $600,000. Gounod's *Faust* was presented on the opening night (Oct. 22, 1883), with Christine Nilsson and Italo Campanini heading a cast that included Sofia Scalchi and Giuseppe Del Puente. On the second night, October 24, Marcella Sembrich appeared for the first time in America, in Donizetti's *Lucia di Lammermoor.*

The stockholders directly sponsored the second season, under the leadership of Leopold Damrosch. The latter gave all performances in German, predominantly of Wagner and other German composers, but including also works by Meyerbeer, Rossini, Halévy, and Auber. Amalia Materna, Marianne Brandt, and Anton Schott were among the singers.

A fire destroyed much of the building back of the stage in August 1892, and the following season was consequently omitted. Abbey, Schoeffel, and Grau leased the house again in 1893. The Metropolitan Opera-House Company, Ltd., was reorganized at this time as the Metropolitan Opera and Real Estate Company. Emma Calvé, Nellie Melba, and Pol Plançon joined the company when the house reopened, and all-star casts distinguished many performances.

The triumvirate managing the company dissolved in 1896, and the house remained empty until 1898, when Grau took charge alone. Ernestine Schumann-Heink and Antonio Scotti then joined the company, and Sembrich and Nordica returned, with the result that the next two seasons achieved unprecedented brilliance.

Edmund C. Stanton became executive director when Damrosch died in 1885, and Anton Seidl and Walter Damrosch, son of Leopold Damrosch, became first and second conductors respectively. Distinguished additions to the roster of singers during this regime included Lilli Lehmann, Emil Fischer, and Max Alvary. First American performances were given of *Die Meistersinger, Tristan und Isolde, Das Rheingold, Siegfried,* and *Die Götterdämmerung.*

The season of 1891–1892 was directed by a triumvirate consisting of Henry E. Abbey (who had been the first director), John B. Schoeffel, and Maurice Grau; and the organization's roster of singers was supplemented by Lillian Nordica, Emma Eames, Emma Albani, and the de Reszke brothers, Jean and Édouard.

When Grau retired because of ill-health in 1903, the Conried Metropolitan Opera Company was formed on a stockholding basis. The new organization had 12 directors headed by Heinrich Conried, who held $150,000 worth of the capitalized amount, and was paid an annual salary of $20,000. During Conried's regime, Wagner's *Parsifal* was performed for the first time anywhere outside of Bayreuth; and Enrico Caruso made his American debut in Verdi's *Rigoletto* (1903), thereafter remaining, until his death 18 years later, the chief attraction of the house. Richard Strauss' *Salome,* with Olive Fremstad as the exotic princess, achieved its American premiere in 1907, but the work was so violently assailed by clergy and critics for immorality that it was banished from the repertory, after one performance, until 1934. Puccini's *Madama Butterfly* was first sung at the Metropolitan on Feb. 11, 1907, with a cast that included Geraldine Farrar, Louise Homer, Caruso, and Scotti.

Conried resigned on Feb. 11, 1908, and the organization then became known, for the first time, as the Metropolitan Opera Company. A joint management was formed. Giulio Gatti-Casazza, who had been general director of La Scala at Milan, was appointed general manager, and Andreas Dippel, who had sung leading tenor roles with the organization for some time, became administrative manager. Gatti-Casazza brought Arturo Toscanini with him from La Scala as chief conductor, and the latter soon became extremely popular. Gustav Mahler conducted the German wing. However, the double management proved unsatisfactory, and after two years, Dippel resigned in order to assume management of the Philadelphia-Chicago Opera Company. Toscanini resigned at the end of the 1914–1915 season because of retrenchments which affected the artistry of performances which he conducted; and when Gatti-Casazza refused to resign with him, the two men became estranged. A reconciliation was not effected between them until April 1932. Meanwhile, the Metropolitan had made every possible effort to induce Toscanini to return, but without success.

Following the entry of the United States into World War I in April 1917, the contracts of a number of German artists were canceled, and German works were dropped from the repertory until Feb. 19, 1920, when *Parsifal* was produced in English, after which the German repertory was resumed. Caruso died on Aug. 2, 1921, and Geraldine Farrar retired the following year.

The economic depression which began in 1929 made itself felt at the Metropolitan in 1931, when a cut of 10 per cent in salary was accepted by most of the personnel. Otto H. Kahn, who had been a member of the board of directors since 1903, and chairman of the majority stockholders' committee since 1924, resigned as both chairman and president of the Metropolitan Opera Company on Oct. 26, 1931.

Much wealthy patronage on which the Metropolitan had largely depended for its maintenance was withdrawn at this time, and the organization turned toward the public for support. A campaign for funds from the public raised $150,000 by the spring of 1932, and on March 3 of that year it was announced that the company was being reorganized on a membership instead of a stockholding basis. It was at this time that the name of the organization was changed from the Metropolitan Opera Company to the Metropolitan Opera Association, Inc. The new organization was headed by a triumvirate consisting of Cornelius N. Bliss, George A. Sloan, and Charles M. Spofford.

On March 23, 1932, Paul D. Cravath, chairman of the Metropolitan's directorate, announced that the guaranty fund of $550,000, which had been available for some years at the beginning of every season, had been exhausted by the expenses of the two previous seasons. On April 16 it was announced that the following season would be cut from 24 to 16 weeks, and a further cut in salary was accepted by most of the artists and technicians. On Feb. 9, 1933, the directors of the Metropolitan stated they would be unable to renew the lease on the opera house, expiring May 31, unless the public would contribute a guaranty fund of $300,000. A public "Save the Metropoli-

tan" campaign for funds, headed by the distinguished soprano Lucrezia Bori, was waged by a subsidiary group formed to enlist public support.

The first broadcast from the stage of the Metropolitan during an actual performance had been made on April 21, 1931, by the League of Composers, presenting Stravinsky's *Oedipus Rex*, conducted by Leopold Stokowski. The Metropolitan first broadcast one of its own performances on Dec. 24, 1931, when Humperdinck's *Hänsel und Gretel*, Karl Riedel conducting, was performed. This experiment proved so successful that Saturday afternoon performances were thereafter broadcast regularly as a sustaining program, a factor which proved invaluable to the Metropolitan in its 1933 campaign for funds from the public. The Juilliard Foundation, which had contributed $5,000 to the previous year's campaign, now contributed $50,000 in return for special privileges, and other large sums were contributed, including $25,000 donated by the Carnegie Corporation. The quota of $300,000 was fulfilled, the season, however, being cut to 14 weeks.

To the 1934 campaign the Juilliard Foundation contributed $40,000; and in 1935 the same foundation pledged $150,000, the Metropolitan raising an additional $100,000. Public interest and attendance were greatly stimulated by the Metropolitan Opera Guild, a membership organization founded in 1935 by Mrs. August Belmont. This organization also made it possible during the first 12 years of the project for over 125,000 high school students to witness performances of grand opera at the Metropolitan at prices ordinarily charged for motion pictures.

Other factors working toward the broadening interest in opera were nationwide broadcasts, made with a sustaining program for the first two seasons, namely 1931–1932 and 1932–1933. During the next season of 1933–1934, the broadcast was sponsored by the American Tobacco Company, and the following year by the Lambert Pharmaceutical Company. Then, for five years, they were carried as a sustaining program, sponsored by the Radio Broadcasting Company of America, starting with the 1936–1937 season. The Texas Company began sponsoring them in 1940–1941. From the beginning, Milton Cross during this period was either the announcer or commentator.

Public interest received additional stimulus after 1935 from Kirsten Flagstad's phenomenal singing of Wagnerian roles. Flagstad made her first appearance at the Metropolitan as Sieglinde in *Die Walküre* on Feb. 2, 1935. The productions in which she participated thereafter, together with Lauritz Melchior, provided the public with the most exhilarating performances of Wagner heard at the Metropolitan in many years.

Gatti-Casazza's regime ended when his contract expired in May 1935. Singers who had become popular during his administration included Caruso, Farrar, Elisabeth Rethberg, Maria Jeritza, Rosa Ponselle, Frieda Hempel, Lucrezia Bori, Frances Alda, Margarete Matzenauer, Louise Homer, Margarete Ober, Sophie Braslau, Giovanni Martinelli, Beniamino Gigli, Feodor Chaliapin, Friedrich Schorr, Clarence Whitehill, Edward Johnson, John Charles Thomas, Lawrence Tibbett, Lauritz Melchior, Kirsten Flagstad, and Ezio Pinza.

On Gatti-Casazza's retirement, Herbert Witherspoon, who had previously sung bass roles at the Metropolitan and, more recently, had functioned as director of the Chicago Opera and as a member of the faculty of the Juilliard Graduate School, was appointed director of the Metropolitan Opera Association. Edward Ziegler, assistant to Gatti-Casazza for many years, remained at his post. Edward Johnson, who had sung tenor roles at the Metropolitan since 1922, was enlisted as assistant general manager, to direct a series of supplementary spring sessions, but became general director of the Metropolitan Opera Association when Witherspoon died of a heart attack on May 10, 1935.

Following the change of administration in 1932, the policy of the Metropolitan broadened in certain respects. More native singers were used; occasional performances in English were introduced; more attention was paid to the concept of opera as musical theater, with emphasis on the ensemble; and a more balanced repertory was established. Singers who achieved popularity under Edward Johnson's administration include Lotte Lehmann, Helen Traubel, Bidu Sayao, Marjorie Lawrence, Zinka Milanov, Eleanor Steber, Licia Albanese, Kerstin Thorborg, Bruna Castagna, Risë Stevens, Gertrud Wettergren, Enid Szantho, Gladys Swarthout, Emanuel List, Nicola Moscona, Set Svanholm, Leonard Warren, Jussi Bjoerling, John Brownlee, Charles Kullman, Jan Peerce, and Ferruccio Tagliavini. Prominent conductors during this era included Artur Bodansky, Thomas Beecham, Georg Szell, and Bruno Walter.

As a producing organization, the Metropolitan in 1947 was still handicapped by the limitations of its large, outwardly unsightly, inconvenient, old-fashioned theater, which seated 3,389 people in five balconies and the main floor (210 in the single tier of boxes), and provided standing room for 380 persons. The theater was antiquated in conception even before it was built, Wagner's model theater at Bayreuth having surpassed all other opera houses in design a decade earlier. The architect of the Metropolitan Opera House was Josiah Cleaveland Cady, who had never designed a theater and is reported to have boasted that he "had never entered a playhouse." The interior has always been luxuriously furnished in the tradition of the Old World opera houses, but the plain, homely, yellow-brick façade, ostensibly in Italian Renaissance style with Romanesque panels, eventually earned the building the affectionate title of The Warehouse. The first figured gold damask curtains and red draperies were hung in 1905; a new gold curtain was hung in 1940. The stage, with its trap doors, elevators, hand ropes for scene shifting, and other trappings, had become as antiquated in 1947 as its five stories of dressing rooms, offices, and studios.

Television was first used at the Metropolitan on March 10, 1940, when one act of Leoncavallo's *I Pagliacci* was televised.

In 1946 the Metropolitan signed a contract with the Columbia Recording Corporation to record operas directly from the stage of the Metropolitan Opera House in the same manner that they are presented in performance.

METTERNICH, mĕt'tĕr-nĭH, **Clemens Wenzel Nepomuk Lothar**, PRINCE, Austrian statesman: b. Coblenz, May 15, 1773; d. Vienna,

June 11, 1859. He was educated at Strasbourg; when only 17 represented the Westphalian princes at the coronation of Leopold II; settled in Vienna in 1794; and asured himself a place in diplomacy by marrying the granddaughter of the Austrian chancellor, Count Wanzel von Kaunitz, in 1795. This marriage not only gave him entry to the best society, but brought wealth, and at the Congress of Rastatt he represented the Westphalian collegium, where he served his apprenticeship in politics. In 1801 he was sent to Dresden by Austria; two years later to Berlin; there a part of his mission was to cultivate the friendship of the French ambassador. He did this so well that that official induced Napoleon to suggest to Austria that Metternich would be a most acceptable representative at the Tuileries; and so in 1806 he was sent to Paris, where he ingratiated himself with Caroline Murat, sister to Napoleon, and with Prince Charles Maurice de Talleyrand. On the outbreak of the war between France and Austria, Metternich was put to much personal inconvenience by Napoleon, who forcibly detained him for some time. Thereafter he entered eagerly into the anti-Napoleonic league; assisted in the formation of the Quadruple Alliance; and as Germany proved successful, took no part in the national sentiment which arose, but directed himself solely to the aggrandizement of Austria, hence doing his best to preserve the French boundaries as they had been and to render Austria the only gainer among the powers by the reapportionment of Europe. He is credited with having planned and brought about the marriage of Napoleon and Marie Louise. In the years that followed he carried things his own way in Austria, planned the Holy Alliance and was extremely reactionary in his internal and foreign policies. In the difficult times of Napoleon's supremacy and his fall Metternich guided Austrian policies with a masterly hand. As a diplomatist he was the equal of any of his time. In 1814 he visited England and formed the Quadruple Alliance. He was the master spirit at the Congress of Vienna and for 15 years thereafter was the leading statesman of Europe. The Revolution of 1830 in France showed the ill-success of his program; and the risings of 1848 and the insurrection in Vienna itself made it necessary for the Emperor Ferdinand to demand his resignation. He kept some power even then, his counsel being frequently sought.

C., *Metternich, Life and Career* (New York 1911); Buckland, C., *Metternich and the British Government 1809–13* (London 1932); Auernheimer, R., *Prince Metternich, Statesman and Lover* (Toronto 1940); Cecil, A., *Metternich 1773–1859: a Study of the Period and Personality* (London 1943).

METUCHEN, mĕ-tŭch'ĕn, borough and residential suburb, New Jersey, in Middlesex County, five miles west-northwest of Perth Amboy; altitude 100 feet. It is served by the Pennsylvania Railroad. Manufactures include insulation materials, metal products, and chemicals. Pop. (1950) 9,879.

METZ, mĕts, city, France, capital of Moselle Department, on the junction of the Moselle and Seille rivers, 178 miles east-northeast of Paris; an important fortress and center of control of a group of forts. Its manufactures include woolens, cottons, hosiery, hats, muslin, glue, and leather, as well as machine-tools, elevators, agricultural equipment, household articles. It has also printing and brewing establishments.

History.—Metz was anciently known as Divodurum; later the Romans gave it the name Mediomatrica; under the Gallo-Romans (1st and 2d century) it was called Mettis, of which Metz is a contraction. The Romans built military roads through the territory, and a fine aqueduct, of which traces remain. It was sacked by Attila in the 5th century, and, after the retirement of the Huns, the Franks occupied Metz and made it the capital of Austrasia. In 870 it was included in East Francia, and developed under German influence. Its prosperity increased, and in the 13th century, as a free imperial city, it attained the zenith of its prosperity. It was taken by the French in 1552, and Charles IV issued there, in that same year, the Golden Bull. The Peace of Westphalia (1648) confirmed the rights of the French to own Metz, together with the rest of Alsace-Lorraine.

The peaceful existence of this territory came to an end in 1870 with the outbreak of the Franco-Prussian War, when several battles were fought under the walls of Metz and in its neighborhood. The town capitulated after a two-months siege on Oct. 28 with 180,000 officers and men under the command of Marshal Achille Bazaine. It was included in the cession of territory to Germany at the peace of 1871.

After World War I the Peace of Versailles (1919) restored Metz to France. But during World War II it was for more than four years once more under German occupation. It was liberated on Nov. 19, 1944 by the American Third Army.

Metz has a handsome cathedral of late Gothic design, and several other ancient churches and monuments, among them the Palais de Justice. On its wall a bas-relief commemorates the treaties of commerce and of mutual defense between America and France negotiated by Benjamin Franklin in 1778. A monument to Lafayette by the American sculptor Paul Weyland Bartlett, commemorating American participation in liberating Metz during World War I, was destroyed by the Germans in World War II. Pop. (1946) 65,472.

MEUDON, mŭ'dôn, commune, France, in the Department of Seine-et-Oise, southwest of Paris. It had formerly a fine château, built by Louis XIV, surrounded by the Forêt de Meudon, still a favorite holiday resort of the Parisians. This château, redecorated in 1812 by Napoleon I for Marie Louise, was a residence of the Napoleons under the Second Empire, but was ruined during the siege of Paris in 1870. An astronomical observatory has since been established in the remains of the castle. Meudon has glass works, bleach fields, and extensive government munition works. Rabelais was briefly curé of Meudon. Pop. (1946) 20,749.

MEUNIER, mŭ-nyā', **Constantin,** Belgian artist: b. Brussels, Belgium, April 12, 1831; d. there, April 4, 1905. An historical and genre painter, he first studied sculpture at the Brussels Academy and with C. A. Fraikin, then painting as a pupil of F. J. Navez. He turned from religious and historical subjects to vividly realistic depictions of life in the colliery district amid whose unlovely surround-

ings he long made his home. His *Martyrdom of St. Stephen* in the Ghent Museum is quite in the spirit of Ribera and shocks the mind by its brutal literalness. *The Peasants' Rebellion* is an example of his energy and force as a realist in modern life. His statue *The Lost Son* is in the Berlin National Gallery.

MEURICE, mû-rēs', **Francois Paul,** French dramatist: b. Paris, France, 1820; d. there, Dec. 11, 1905. He was educated at the Collége Charlemagne and entered upon a literary career. He worked for a time in collaboration with Jean Dumas, with whom he made a translation of Hamlet, and was entrusted by Victor Hugo, his brother-in-law, with the publication of his complete works (46 vols., 1880–1885). He published *Benvenuto Cellini* (1852); *Fanfan la Tulipe* (1858); *Cadio* (1868); *Le Songe de l'Amour* (1889).

MEURSIUS, mûr'sē-ŭs, **Johannes** (Latin form of Jan de Meurs), Dutch scholar and historian: b. Lovsduinen, Feb. 9, 1579; d. Sept. 20, 1639. Besides *Glossarium Graeco-Barbarum* (1614); and *Athenae Batavae* (1625); for his edition of Greek authors he wrote numerous introductory essays which J. F. Gronovius reprinted in *Thesaurus Antiquitatum Graecarum.* His complete works were edited by Lami, 12 vols. (Florence 1741–1763).

MEUSE (Flem. *Maes;* Du. *Maas*), a river which rises in northeastern France in the department of Haute-Marne and flows in a generally northerly course through France, Belgium and Holland into the North Sea where it forms a common delta with the Rhine. Its source is on the plateau of Langres, about six miles west-northwest of Bourbonne-les-Bains. Above Neufchâteau (Vosges) it runs underground for a distance of over three miles. In the neighborhood of Maastricht it forms a 31-mile sector of the boundary between Belgium and Holland. Its principal affluents are the Chiers, Semois, Lesse, Sambre, Ourthe and Roer. Parts of its course in Belgium and Holland have been canalized. The principal French cities on the Meuse are Verdun, Sedan, Mézières and Givet; Belgian cities are Dinant, Namur, Huy, and Liége; Dutch cities are Maastricht, Roermond, Venlo, Dordrecht, and Rotterdam. During World War I the upper valley of the Meuse was the scene of the most sanguinary battles, including the Battle of Verdun.

MEUSE, a northeastern department of France having an area of 2,410 square miles. The capital is Bar-le-Duc. Meuse is bounded on the north by Belgium and the department of Ardennes; east by Meurthe-et-Moselle; south by Vosges and Haute-Marne; and west by Marne and Ardennes. When France was departmentalized during the Revolution, the Meuse was constituted from a portion of Lorraine, that is, from parts of the Three Bishoprics, the Barrois and Clermontais, and derived its name from the River Meuse (q.v.) which flows centrally through it from south to north-northwest. Approximately half the department is contained in the Meuse basin. The northeastern part comprises the valley of the Orne, a tributary of the Moselle, and the Chiers. In the western part the Aisne with its tributary the Aire take their rise, the mingled waters flowing west to join the Seine. Here too is the Ornain, affluent of the Saulx, their waters debouching into the Marne. Main waterways are the canal connecting the Marne and Rhine and the Eastern Canal, which parallels the Meuse, the two having a length of 145 miles.

A rolling fertile terrain, with a rather large forested area (about one quarter), the department has no mountains. Its highest elevation, in the southwest on the line of the watershed dividing the Seine and Meuse basins, rises to only 1,388 feet. The main crops are wheat, oats, rye, barley, and potatoes. Viticulture is a minor activity. Industrial activities include lumbering, quarrying, paper milling, cheese manufactures, glass works, distilleries and flour mills. At Ligny-en-Barrois scientific instruments are manufactured. The department is divided into four arrondisements: Bar-le-Duc, Commercy, Verdun, and St. Mihiel; and these are divided into 28 cantons and 586 communes. Pop. (1946) 188,786.

MEXCALA, mâs-kä'lä, or **RIO DE LAS BALSAS,** rē'ô thâ läz väl'säs, river, Mexico, in the southern part, which has its rise in the mountains southeast of the City of Mexico, and flows generally south and west for 426 miles to the Pacific. It is on the boundary line between the states of Michoacán and Guerrero. The port of Zacatula is at its mouth. It is a swift-flowing stream, and has a number of low cascades and rapids.

MEXIA, mĕ-hā'ä, city, Texas, in Limestone County; altitude 534 feet; 29 miles southeast of Corsicana; on the Southern Pacific, and Burlington-Rock Island railroads. In 1920 there was an oil boom here, but now the oil industries are second to agriculture in contribution to the city's prosperity, and cottonseed oil, textiles, and machinery are the principal products of its industry. It has the commission form of government. Pop. (1940) 6,410; (1950) 6,627.

MEXICALI, mĕ-hē-kä'lē, town, Mexico, capital of Northern Territory, Lower California, near Calexico, Calif.; agricultural center in the Imperial Valley area. Pop. (1950) 64,658.

MEXICAN ARCHAEOLOGY. See Mexico—*Ethnology.*

MEXICAN BOLL WEEVIL. See Boll Weevil.

MEXICAN HAIRLESS DOG, a small terrier-like dog, of uncertain origin, without hair except a tuft on the crown of the head, another on the tail and a few scattering wisps on the body; the skin is grayish black, wrinkled and dry. Clavigero describes a large hairless dog found among the Mexicans by the Spanish conquerors, whose puppies were esteemed as an edible delicacy; and others are recorded as having occurred in ancient Peru and on various of the West Indian islands.

MEXICAN JUMPING BEAN. See Jumping Beans.

MEXICAN LITERATURE. See Mexico—*Literature.*

MEXICAN ONYX, a stained and banded

variety of calcite or aragonite. It is not true onyx.

MEXICAN SUBREGION, a faunal district of the Neotropical region embracing the low hot coast region of Mexico. See ZOOGEOGRAPHY.

MEXICAN TEA. See GOOSEFOOT.

MEXICAN WAR. The annexation of Texas in 1845 laid the foundation for the war with Mexico. Although Texas had been for many years practically free, and had been recognized by the United States, England, France and other countries, yet Mexico still refused to acknowledge its independence. When therefore the United States proposed to admit Texas into the Union, Mexico gave warning that the annexation would be equivalent to a declaration of war, and March 6, 1845 protested, and soon afterward withdrew her minister and severed diplomatic relations. Her acts, however, scarcely justified her threats, as at that time at least little or no preparation was made for war. It has, therefore, been claimed that had the American government used a conciliatory policy, peace might have been preserved and friendly relations re-established.

At the moment, however, the Mexican people and authorities were in a rather belligerent attitude, due in part to pride, and in part to an expectation that the United States would soon be involved in a war with Great Britain over the Oregon boundary, in which case Mexico would have a powerful ally to aid her. Did President Polk at this point seek to strengthen this hope in the minds of the Mexicans, intending at the proper moment to make a compromise and peace with England, as was done, and thus leave Mexico at the mercy of the United States? Perhaps history can never answer the question, but events at least seemed to march in harmony with the thought. For Mexico soon found herself in the dilemma that she must either sell California to the United States, receiving in return a goodly sum of money to appease her pride, or engage in a war to sustain her honor and territorial integrity. Mexico bravely, but perhaps not wisely, chose the latter alternative, not fully realizing the inequality of the contestants, nor the depth of the humiliation to which she would be subjected. Doubtless President Polk preferred to acquire California without war; but its acquisition was to be the principal measure of his administration. Hence if war was the only means to secure it, war it must be; at least enough to get possession of the desired territory.

Causes of the War.—The immediate occasion of the war was the dispute in regard to the western boundary of Texas. Proclaiming her independence in 1836 Texas asserted that her western boundary was the Rio Grande to its source, thence due north to the 42d degree of north latitude. The following year the United States recognized her independence, and in December 1845, by a joint resolution, admitted her into the Union as a state, providing that boundary disputes were to be settled by the United States. President Polk accepted the boundary line claimed by Texas, and Jan. 13, 1846 ordered Gen. Zachary Taylor to march to the eastern bank of the Rio Grande as the western boundary of the United States. Mexico insisted that the Nueces River—100 miles eastward—was the true western boundary of Texas, and therefore that General Taylor was now on Mexican soil. On April 25, 1846, the first blood was shed in a conflict between a band of Mexican troops that had crossed to the eastern side of the Rio Grande and a company of American soldiers. The news of this action was immediately communicated by General Taylor to President Polk, who sent his now noted message to Congress, asserting that war was begun by the act of Mexico on United States soil. Congress accepted, after a stormy debate in the Senate, the President's statement, and war was recognized as existing.

Other causes than the two already noted were also at work, and help to make a decision in regard to the justness of the war still more difficult. Mexico for many years had been in a chronic state of revolution. The natural result followed. American citizens in Mexico sustained property losses and doubtless were frequently unjustly arrested and even imprisoned. Claims arising from these causes had been in part settled under a convention of 1840; but many of them were still pending. Some were just; more, either unjust or extravagant in amount. President Polk united these unsettled claims with the boundary question, and demanded that Mexico receive an envoy extraordinary with power to settle both—on its face an eminently fair proposition. On the other hand, Mexico professed to be ready to receive an ambassador to settle the boundary dispute, but declined to receive John Slidell as United States minister, when he was commissioned to settle all disputes, insisting that the two questions were distinct in kind and origin and should not be united. President Polk in his message asserted that this action of Mexico was in violation of her promise to receive a minister, and hence justified his administration in its measures, and forced him to take possession of the disputed territory.

The need of more slave territory was perhaps another factor in causing the war. At least many from the South took an aggressive position on all questions in dispute between the two countries and thus made a peaceable settlement more difficult. Both the economic and the political reasons for more territory began to be felt by 1846—the one to have new soil over which to spread the land-exhausting system of slavery; and the other to have new territory out of which to carve new slave states that the equilibrium between slave and free states might be maintained. Some other forces tending to arouse the war and aggressive spirit may be noted. The cry of "manifest destiny" played a part. Many, especially in the West, felt that the Pacific Ocean was the natural western boundary of the United States. They also demanded the "Golden Gate" that commerce might be opened up with the Orient. The two great parties—the Whigs and the Democrats—divided quite sharply on the question; in fact so completely that the war became almost a party, instead of a national, issue. The Democrats, as a rule, supported the administration and its claim that the war was just. The Whigs, on the contrary, asserted that it was a most unholy and unrighteous war, and characterized it as Polk's war. Abraham Lincoln, entering Congress in 1847, became a severe critic of the policy pursued, while Thomas Corwin of Ohio went so far

as to use this language: "If I were a Mexican I would tell you, 'Have you not room in your own country to bury your dead men? If you come into mine we will greet you with bloody hands, and welcome you to hospitable graves.'"

President Polk summarized his reasons for recommending that Congress recognize war as existing as follows: "The grievous wrongs perpetrated by Mexico upon our citizens throughout a long period of years remain unredressed; and solemn treaties . . . have been disregarded. . . . Our commerce with Mexico has been almost annihilated." He then adds: "As war exists, and . . . exists by the act of Mexico herself, we are called upon, by every consideration of duty and patriotism, to vindicate, with decision the honor, the rights, and the interests of our country."

The Campaigns.—The war with Mexico was accepted as a fact by Congress, May 13, 1846. There were four principal fields of action in its prosecution. (1) Along the Rio Grande, under the command of Gen. Zachary Taylor; (2) in California, where Capt. John Charles Frémont and Commodore Robert Field Stockton were in command; (3) in New Mexico, with Colonel Stephen Watts Kearny leading the United States forces; and (4) from Veracruz to Mexico City, under the command of Gen. Winfield Scott, the commander in chief of the United States armies. Everywhere success attended the arms of the United States. Perhaps it was the first war in history, lasting two years, in which no defeat was sustained by one party, and no victory won by the other.

General Taylor defeated the Mexican troops at Palo Alto, May 8, 1846; at Resaca de la Palma the following day, and captured Matamoros on the 18th. He remained near that city for some weeks to recruit his army and prepare to advance into the interior. On September 24 he entered Monterrey, after a siege of four days, and a gallant resistance by the Mexicans. Taylor's most famous victory, however, was won Feb. 22–23, 1847, at Buena Vista. General Scott gave orders, which fell into the hands of Antonio López de Santa Anna, the Mexican general, for General Taylor to send some nine regiments to aid Scott in his proposed attack on Veracruz. Santa Anna immediately marched his whole command against Taylor, expecting to crush him in this weakened condition. It was 20,000 men against about 5,000. But the skill of Taylor, the persistence of his army, the organization and equipment of the United States troops, won a great victory. Taylor became the hero of the hour, and Buena Vista made him an irresistible presidential candidate.

Frémont's course in California has been a subject of keen controversy. As leader of an exploring expedition he was already in northern California, and early in 1846 was recalled to the Sacramento Valley. California was the goal of the political policy of Polk's administration. The means to secure its acquisition were uncertain. It might be gained by war; or by filling the territory with settlers from the United States, who in course of time might bring it into the Union as Texas had already been annexed; or it might be effected by securing the goodwill of the native Californians who were already jealous of Mexican rule. The latter policy seems to have been the one adopted by the administration. The United States consul at Monterey, California, Thomas Oliver Larkin, was developing this policy with a good prospect of success, it is claimed, when Frémont appeared on the scene. He seems to have developed a fourth policy, namely, the establishment of an independent government under the control of settlers from the United States in the Sacramento Valley. This movement resulted in the so-called Bear Flag Republic, and virtual civil war between the native Californians and the newer settlers. At this moment the Mexican War began and the Bear Flag was replaced by the Stars and Stripes. It has been claimed by some California historians that Frémont's course, had not the Mexican War come at the moment it did, might have lost California to the United States. The native Californians, alienated as they were by his course, might have put themselves under an English protectorate in revenge for the treatment accorded them. Be this as it may, by the end of 1846 all California was conquered and held by United States troops, and Frémont was regarded as the hero who had won the "Golden Gate" by his energy and decision.

Santa Fé was captured by Colonel Kearny, Aug. 18, 1846, and New Mexico secured with almost no loss of life. By the end of the year, therefore, all the territory that the administration desired was in the possession of its armies, but Mexico was still unconquered.

Scott had been chafing in Washington during the summer and fall of 1846 while Taylor was winning his brilliant victories. He asked to go to the front to assume chief command, but the administration retained him at the capital under the plea of needing his advice. As it happened this Democratic war was officered by Whig generals. Scott had already been a candidate for the Whig nomination for the presidency. The charge was now made that Scott was kept from command for fear that success might make him a more formidable candidate in 1848. Finally, when he was sent to the front in January 1847, the cry was raised that the purpose was to dim the luster of Taylor's victories, or at least to divide the popular support between the two generals in such a way as to destroy the political prospects of both.

General Scott invested Veracruz in March 1847, and by the 27th had captured the fortress of San Juan de Ulúa, which had been thought to be almost impregnable, and was ready to enter the city. On April 8 he started into the interior, and on the 18th captured Cerro Gordo; the 19th, Jalapa; and the 22d, Perote. On May 15 he entered the important city of Puebla. Remaining here for some weeks he again advanced, in August, toward the capital, and on the 10th came in sight of the city. Two important victories were won August 20—at Contreras and at Churubusco. He captured Molino del Rey, September 8, and the victory of Chapultepec, September 12–13, gave him Mexico City itself, which he entered on September 14 with an army of only 6,000 men.

The war was practically over, but the victory was so complete that it began to be a question whether there was any government left with sufficient power to negotiate a treaty of peace. An agitation began with friends both in and out of Congress, as well as in the cabinet, looking to the annexation of the whole of Mexico. John C. Calhoun on the one hand, Daniel Webster and a majority of the Whigs on the other, joined

hands to defeat this plan. President Polk was finally forced to make the ultimate decision. Nicholas Trist was sent in March 1847 to Mexico to make a treaty of peace. Failing, he was ordered in the fall to return to Washington; but disobeying instructions he remained in Mexico, and on Feb. 2, 1848, concluded a treaty of peace in harmony with his original instructions. The administration was in a quandary. To ratify meant to condone the disobedience of Trist. To reject meant a prolongation of the war, and time to perfect the intrigue for the annexation of "All Mexico." President Polk, after some hesitation, decided to send the treaty to the Senate for its consideration. Received February 23, it was ratified, after some amendments, March 10, by a vote of 38 to 14. On May 30, ratifications were exchanged and the war was at an end.

The Mexicans had fought bravely, even stubbornly and at times skillfully, yet in every contest, even when the odds were greatly in their favor, without a single victory. In part superior leadership and training won for the soldiers of the northern republic; in part their cooler and more persistent character; but in the main it was not bravery, nor generalship, nor even character that won. It was science and education applied in the equipment of the armies, the guns of the soldiers, the cannon, and the powder in the arsenals which made the one so much more effective than the other that the most daring bravery was no counterpoise.

The Treaty of Peace.—The treaty of Guadalupe Hidalgo gave to the administration of President Polk the territory that his diary informs us he intended to acquire, California and New Mexico. Mexico in return for the loss of its fairest northern provinces was paid $15,000,000, and released from all claims of all kinds held by citizens of the United States against her, estimated at $3,250,000, which the United States assumed. Boundary lines were drawn, and provision made in regard to other questions at issue between the two countries.

Results.—Usually successfully waged wars redound to the credit of the party in power. In this case, however, the Democratic Party, the author and supporter of the war, was defeated by the Whig Party, the party of opposition and criticism, in the presidential election of 1848. The Whigs made use of the popularity of a successful general (Taylor) to defeat the party that had made his glory possible. Evidently the people were ready to accept the fruits of the war, but also ready to punish the party they believed had wrought in a wrong manner.

A large number of young officers, destined to renown in later years, proved their worth in this war. Ulysses S. Grant and William T. Sherman, Robert E. Lee, "Stonewall" Jackson, and Jefferson Davis, in the great Civil War, foreshadowed, in this Mexican struggle, the greatness that was to be theirs in the "days that tried men's souls" from 1861 to 1865.

The acquisition of some 522,568 square miles of territory—about one sixth of the modern continental United States—was the most important immediate as well as remote result. It was important in the issues that its acquisition precipitated. Should it be slave or free territory? Who should determine its institutions? Out of this question grew the larger one, who had the right to control the institutions of the territories in general? To settle the first question David Wilmot, a Democrat of Pennsylvania, proposed the celebrated Wilmot Proviso which would exclude slavery forever from all territory acquired from Mexico. Four long years of intense and bitter debate followed. This question and a series of others were settled temporarily in the Compromise of 1850. The second question was answered by the phrase "nonintervention," which meant, or soon came to mean, one thing to Douglas and the Northern Democrats, and another to Davis and the South. Three main theories were evolved or defended in answer to the third query: (1) that Congress had the right to control the institutions of the territories and could make them slave or free at its will; (2) the Dickinson-Cass-Douglas doctrine of popular or "squatter" sovereignty—the doctrine that the people of a territory themselves, while yet in a territorial status, determined their own institutions; (3) the radical Southern view that slaves were property, and, as property, might be taken into any territory—the common public domain of the states—with no constitutional power anywhere to hinder or prevent.

The new territory was important secondly in its industrial and political effect on the nation. The United States now had an outlook on the Pacific Ocean comparable to that on the Atlantic. China, Japan and the Orient were brought within the circle of its influence. Conditions favorable to further expansion were prepared. In addition to the great effect on commerce thus prefigured, that on wealth and industry was not less. The gold, silver, copper, and other mineral wealth of the Rocky Mountain region was turned into the pockets of the people of the United States. This vast addition of territory and wealth tended also to emphasize national pride and ambition; to arouse a still more intense belief in "manifest destiny"; to develop a more optimistic tone, and perhaps also to produce a more materialistic spirit.

HOWARD W. CALDWELL,
Late Professor of American History, University of Nebraska.

H., *Rehearsal for Conflict, the War with Mexico* (New York 1947); Henry, R. S., *The Story of the Mexican War* (New York 1950).

MEXICO, mĕk'sĭ-kō, Span. mĕ'hĕ-kô (officially LOS ESTADOS UNIDOS MEXICANOS; The Mexican United States), republic, is bounded to the north by the United States of America, and to the south and southeast by Guatemala and British Honduras. Within the country, the name México is chiefly reserved for the capital, known to the English-speaking world as Mexico City; the nation as a whole being generally referred to simply as *la república* (the republic).

The most important features of geographical relief are the lofty Central Plateau bordered by two mountain ranges and these ranges themselves, the Sierra Madre Oriental on the east and the Sierra Madre Occidental on the west.

Although Mexico is usually considered as being in North America, it is perhaps more accurate from the point of view of physical geogra-

phy to include in North America only that portion between the southern border of the United States and the Sierra Volcánica Transversal (see section *The Land*); assigning the territory south of this sierra to Central America. The national territory is divided into almost equal parts by the Tropic of Cancer, or latitude 23°27′N., which transverses it.

The name and the national emblem of Mexico are derived from the Aztecs who, according to tradition, departed from Aztlan (thought to be in the northwestern part of the republic) in 820 A.D., and after a peregrination of many centuries arrived at what is today the Valley of Mexico. It is believed that they chose this site on the banks of what was then the principal lake, in response to a prophecy which instructed them to settle where they saw an eagle holding a serpent in its claws. The name Mexico was derived from the word Mexitli—another name for the Aztec god of war, Huitzilopochtli—to which was added the suffix *co*, signifying "place."

Coat of arms.

The eagle seen by the Aztecs was conserved as a symbol through the years, and when independence was achieved in 1821 it was adopted as the national emblem, which it is today. The flag, consisting of three wide vertical stripes, green at the hoist, white in the center, and red at the fly, with the emblem—the eagle standing on a cactus devouring a serpent—in the center, dates from 1821 when the Plan of Iguala (see section *Mexico from 1810 to 1910*) was approved. A minor change in design was made by an act of April 14, 1823. The words of the national hymn whose first line is *Mexicanos, al grito de guerra* were written by Francisco Gonzáles Bocanegra; and its music, by Jaime Nunó.

Spanish is the official language. The metric system is in use and the monetary unit is the peso, consisting of 100 centavos.

For the convenience of the reader, the historical, political, economic, and social development of Mexico is discussed in the following articles, written by eminent Mexican authorities.

1. THE LAND. Mexico lies south of the United States, and north and west of Guatemala and British Honduras. It is otherwise limited by the Pacific Ocean on the west and by extensions of the Atlantic Ocean—the Gulf of Mexico and Caribbean Sea—on the east. The total length of the coastlines is 6,212 miles. The northernmost point of Mexico is at the confluence of the Gila and Colorado rivers, at latitude 32°41′N. Its southernmost point is the mouth of the Suchiate River at latitude 14°30′N.

The border with the United States was established, following the annexation of Texas by the United States in 1845 and the war with that country in 1846–1848, by the Treaty of Guadalupe Hidalgo, Feb. 2, 1848. This treaty was later modified by the Gadsden Purchase, also known as the Treaty of Mesilla, Dec. 30, 1853, by which the United States annexed other territories of the Mexican states of Sonora and Chihuahua. The frontier with Guatemala was determined by two treaties, of Sept. 27, 1882, and May 19, 1894. The frontier with British Honduras was established by treaty with Great Britain, July 8, 1893.

The calculations of the Dirección de Geografía y Meteorología place the area of Mexico at 760,579 square miles, excluding the continental shelf, which was declared incorporated into the national territory by President Manuel Ávila Camacho, Oct. 30, 1945; the decree being ratified by the legislature in a special session, Jan. 16, 1946. The area of the continental shelf claimed by Mexico is 154,633 square miles.

PHYSIOGRAPHY

Mexico is divided into nine physiographic provinces, as follows:

Northwestern Mexico.—(1) *Peninsula of Lower California.*—This is the continuation of a series of anticlines extending along the western part of the North American continent and comprising the Alaska Range, the Coast Mountains of British Columbia, the Cascade Range, the Sierra Nevada, and the Sierra de Baja (Lower) California. The anticlines of the Sierra de Baja California produced extensive lava flows during the Upper Tertiary period, but the region seems to have remained quiet throughout the Quaternary.

(2) *Gulf of California and Adjacent Lowlands.*—These are the continuation of the depressions, the basin, and range complex found throughout the western part of North America; including the basins of the Yukon, Fraser and Columbia rivers, and the Great Basin of the

western United States. Faulting has been extensive in the Gulf of California. In adjacent plains of the states of Sonora, Sinaloa, and Nayarit are found elongated volcanic edifices of the Tertiary period.

North and Central Mexico and Yucatán Peninsula.—(3) *Sierra Madre Occidental and Sierra Madre Oriental.*—The former, which follows the western coast at some distance inland, is the most important manifestation of relief in Mexico, as well as of the entire continent; being in other places known as the Rocky Mountains. No evidence has been found of volcanic activity during the Quaternary period in the Sierra Madre Occidental, except in the southern part. The foldings of this range take on an east-west orientation, cross the Central Plateau and continue in the Sierra Madre Oriental, which follows the eastern coast at a distance from the Gulf of Mexico. The latter range began to take form during the Upper Middle Cretaceous, as the result of foldings which continued during the Tertiary. Its great elevation is interrupted only here and there from Monterrey to the Isthmus of Tehuantepec. Volcanism was active in the central part of the Sierra Madre Oriental during Quaternary times; elsewhere the range has been quiet.

(4) *Mexican Central Plateau.*—This plateau, lying between the Sierra Madre Occidental and the Sierra Madre Oriental, is the continuation of the Great Plains of the western United States and Canada. It was formed mostly by marine sedimentations during the Cretaceous period, then emerged from the sea during an uplift which continued during Tertiary and Quaternary times. The plateau is crossed by folds of the Sierra Madre Occidental and the Sierra Madre Oriental systems, and by a transverse range beginning in the State of Durango and continuing across the states of Zacatecas, Guanajuato, Querétaro, and Hidalgo to the borders of Puebla. This last is characterized by numerous volcanic edifices, products of the Oligocene and Miocene periods. To the south of this range once again are found isolated plateaus, such as El Bajío (the high valley of the Central Plateau which includes most of Guanajuato and parts of Querétaro, Michoacán, Jalisco, and Aguascalientes) and the so-called valleys of Toluca, Mexico, Tlaxcala, Puebla, and Tehuacán, all of which are limited in the south by the Sierra Volcánica Transversal. Only in this last zone of the Central Plateau do earthquakes still occur.

(5) *Gulf Coastal Plain and Yucatán Peninsula.*—This division is a continuation of the coastal plain which begins east of the Appalachian Mountains and continues into Florida and along the Gulf coast of the United States. It embraces the Mexican states of Tamaulipas, Veracruz, and Tabasco, and the Yucatán Peninsula; then the plain submerges into the Yucatán Channel, later to reappear in Cuba. The uplifting of this coastal plain in Mexico began toward the end of the Cretaceous period and has continued, despite numerous recessions, through the Tertiary and Quaternary. The relief of the region drops precipitously down from the highlands on the west, tapering off into a plain of very slight inclination. Except for some regions of the central and southern parts of Veracruz, which are seismic zones due to their proximity to the tectonic region of southern Mexico, the coastal plain is free of earthquakes in the present era.

(6) *Sierra Volcánica Transversal.*—The Transverse Volcanic Range rises south of the Central Plateau and north of the Balsas Depression. Its historical geology is very similar to that of the neighboring physiographic divisions, with interruptions from time to time by effusions of lava, which have formed a series of lofty volcanic edifices along the 19th meridian from coast to coast. It is a region of tectonic as well as of volcanic earthquakes. The Sierra Volcánica Transversal includes the famous Popocatepetl, Citlaltepetl (Pico de Orizaba), and Colima, old but still active volcanoes, as well as the newer Jorullo and Paricutín.

Southern Mexico.—(7) *Balsas Depression.*—The depression of the Balsas River in the states of Michoacán and Guerrero, with the depressions of the rivers Atoyac (in Puebla), and Nochistlán, Verde, and Tehuantepec (the last three in Oaxaca), is part of a geosyncline which also includes the Gulf of California and the other great depressions of the continent associated with it. This region underwent the same uplifts of the Upper Cretaceous and Tertiary periods as its southern neighbor, the Sierra Madre del Sur. The foldings which formed the depression itself began during the Oligocene and continued into the Quaternary. It is also a region of frequent tectonic earthquakes.

(8) *Sierra Madre del Sur.*—This sierra, which crosses the states of Colima, Michoacán, Guerrero, and Oaxaca, is the continuation of the Sierra de Baja California and the other mountain ranges linked with it. This region experienced an uplift beginning in the Upper Cretaceous period. During the Cenozoic, the uplifting continued, accompanied by the foldings which created the mountainous relief. The present tectonic character of the Sierra Madre del Sur is reflected by frequent earthquakes.

(9) *Isthmus Region and Chiapas.*—The three physiographic divisions described immediately above end at the Isthmus of Tehuantepec, where their physiographic elements taper off to a low altitude and are scarcely distinguishable one from another. Farther east, however, in the State of Chiapas the three phenomena once again appear more pronouncedly, clearly dividing the region into three zones. The mountainous region of the Sierra Septentrional de Chiapas, in the north of that state, is a prolongation of the Sierra Madre Oriental, being prolonged even farther into Guatemala, British Honduras, Cuba, Haiti, the Dominican Republic, and Puerto Rico. The central depression of Chiapas is a continuation of the Balsas Depression and the associated depressions of the states of Oaxaca and Guerrero. This series of depressions continues through Guatemala and British Honduras into the Caribbean, where it is known as the Bartlett Deep. The Sierra Madre de Chiapas, in the west, is a prolongation of the Sierra Madre del Sur which continues across Guatemala and Honduras, later reappearing in Jamaica and Haiti. In this physiographic division, volcanic activity is at present concentrated in the south.

Volcanoes.—Volcanism in Mexico was at its maximum activity during Tertiary times, especially during the Oligocene period, although it has continued to the present. Volcanic activity is concentrated mainly along the 19th meridian of latitude, in the range formed by various volcanic edifices, called the Sierra Volcánica Transversal. The most important volcanoes of this

range, with their approximate heights, are: Colima Volcano (12,984 feet) and the Nevado de Colima (14,108 feet), in western Jalisco; El Quinceo (9,016 feet) and Tancitaro (11,148 feet), in Michoacán; the Nevado de Toluca (14,944 feet), in Mexico State; Cempoala (14,036 feet), in Morelos; Popocatepetl (17,705 feet) and Ixtaccihuatl (17,671 feet), both within sight of Mexico City; Malinche (14,623 feet), between Tlaxcala and Puebla; and Citlaltepetl, or Pico de Orizaba (18,843 feet), the highest point in the republic; and Cofre de Perote (13,475 feet), in Veracruz.

In the Revillagigedo Islands, lying along the 19th parallel in the Pacific, are found Monte Evermann, on Socorro Island, and Monte Gallegos and Monte Tent on Clarión Island. Smaller Mexican volcanoes include: Ceboruco (7,100 feet) and Sanganguey, in Nayarit; Tequila, in Jalisco; Calmini, Virgenes, and Loreto in the Sierra de Baja California; Chacahua, Ometepec, and Pochutla in the Sierra Madre del Sur; the volcanoes of the Tres Marías Islands off the coast of Nayarit; and San Bartolomé, Zontehuitz, San Cristóbal, Hueytepec, and Chicón, in Chiapas. The youngest volcanoes of Mexico are Jorullo (4,331 feet; erupted first in 1759) and Paricutín (in 1943), both in Michoacán.

Rivers and Lakes.—The principal rivers of Mexico, with their alternate names and approximate total lengths, are given in the following paragraphs.

Rivers which drain into the Gulf of California are: the Colorado, most of whose course is in the United States; the Concepción (or Magdalena, 200 miles long); Sonora (250 miles); Yaqui (420 miles); Mayo (220 miles); Fuerte (175 miles—350 miles with its affluent the Verde); Sinaloa (200 miles); and Culiacán (175 miles).

Those entering the Pacific are, in central Mexico, the San Pedro (250 miles—upper course called the Mezquital) and Santiago (600 miles—upper course, above Lake Chapala, called the Lerma). In the south are the Balsas (450 miles—upper course called the Atoyac in Puebla and the Mexcala in Guerrero) and its affluent the Tepalcatepec (150 miles), the Verde (200 miles—upper course called the Atoyac), Tehuantepec (150 miles), and Suchiate (100 miles) on the Guatemala border.

The most important river draining into the Gulf of Mexico in the north is the Rio Grande (or Bravo), most of whose course separates Mexico from the United States. Its chief tributaries from the Mexican side are the Conchos (300 miles) and the Salado (210 miles—upper course called the Sabinas). The San Fernando (170 miles) and Soto la Marina (160 miles) are also in the north. In the central region are the Pánuco (100 miles), which is formed by the junction of the Moctezuma (175 miles) and the Santa María (200 miles)—the lower course of the Pánuco is also called the Tamuín—as well as the Tuxpan (or Tuxpam, 100 miles), Tecolutla (257 miles), and Nautla (162 miles). In the south are the Papaloapan (or Papaloápam, 375 miles—195 miles with its headstream, the Tuxtepec), Coatzacoalcos (175 miles), Grijalva (400 miles—middle course also called Chiapa), and Usumacinta (600 miles—upper course called the Chixoy). The Grijalva and Usumacinta are connected near the coast. The Hondo (150 miles) drains into the Caribbean Sea after forming the border between Quintana Roo and British Honduras.

The Papaloapan is the most important river of Mexico, occupying seventh rank among the rivers of the world in volume of water discharged; the rate at times reaching 8,000 cubic meters per second at Tlacotalpan, where its force is greatest. The Lerma-Santiago River is also of great importance. The Lerma rises in the mountains near Toluca and drains into Lake Chapala, the largest (417 square miles) and one of the most beautiful lakes in Mexico. By way of the Santiago River, Lake Chapala drains into the Pacific, as noted above.

In the interior there are many rivers which do not drain into the ocean but into lakes which have no outlet. In the northwest of the Central Plateau, the Casas Grandes (250 miles long) drains into Lake Guzmán (56 square miles in area); the Santa María (200 miles) into Lake Santa María (30 square miles); and the Carmen (150 miles) into Lake Patos. These three rivers and lakes are in Chihuahua. In the west of the plateau, the Cadena (94 miles) drains into Lake Palomas, Chihuahua. The areas of lakes Patos and Palomas are variable, due to irrigation operations. Also in the west, the Nazas (180 miles) formerly drained into Lake Mayrán, in Coahuila; and the Aguanaval (250 miles), into Lake Viesca, also in Coahuila. These two rivers were dammed, however, and have water only in the rainy season. In Michoacán, lakes Pátzcuaro (100 square miles) and Cuitzeo (160 square miles) have no outlet to the sea; nor has Lake Sayula (79 square miles) in Jalisco.

The Moctezuma River, an affluent of the Pánuco as mentioned above, now drains the ancient lacustrian basins of the Valley of Mexico, where of five lakes, Texcoco, Zumpango, Xaltocán, Chalco, and Xochimilco, the last named is the only survivor, although only Chalco is absolutely dry in all seasons.

Islands.—Mexico possesses numerous islands off both coasts, many of which are uninhabited. The principal islands in the Gulf of Mexico and Caribbean Sea, all of which are populated, are Carmen, on which is the port of Carmen, Campeche; and Cozumel and Mujeres islands off Quintana Roo. Mujeres is notable for being the first Mexican land discovered, by Francisco Fernández de Córdoba on March 1, 1517.

In the Pacific the only populated islands are Cedros (Northern Lower California), which has a plant for packing sea food; Margarita (Southern Lower California), a naval base; and Tiburón, home of the Seri Indians, in the Gulf of California off the coast of Sonora.

Nevertheless, it is in the Pacific that Mexico has her most interesting islands, among them Socorro and Clarión in the Revillagigedos, 300 to 500 miles from the nearest point on the continent.

Guadalupe Island is one of the most interesting islands in the world. Located 180 miles west of northern Lower California, it rises sharply from the abyssal depths of the ocean to an altitude of 4,498 feet. Guadalupe is the home of the only surviving elephant seals (or sea elephants; *Macrorhinus angustirostris*).

Climate and Vegetation.—In general, altitude and rainfall are more important than latitude in determining climate. According to the classification of Wladmir Köppen, the following types of climate are found in Mexico:

(1) Tropical humid climate with rains throughout the year (type Af), in northeastern Chiapas, the southwestern tip of Campeche, southeastern Veracruz, and Tabasco except along the coast. Here the vegetation is tropical rain forest, characterized by angiospermous trees, both monocotyledons and dicotyledons, to which cling lianas or vines and epiphytes or parasitic plants. Among the trees of greatest economic importance are red cedar, mahogany, lignum vitae, quebracho, ceiba, brazilwood, logwood, and sapodilla, as well as tropical fruit trees.

(2) Tropical humid climate with intense monsoon rains in summer (Am), along the Atlantic slopes of the Sierra Madre Oriental, across the State of Veracruz, along the north of the Sierra Septentrional de Chiapas, and in the south of Campeche and Quintana Roo.

The natural vegetation is tropical forest, which is composed of the same class of trees as the tropical rain forest, but without lianas and epiphytes. Thus it is less dense than the rain forest. Among its most important species, in addition to those noted as belonging to the tropical rain forest, are avocados, custard apples, magnolias, guavas, and cacao trees.

The tropical forests of Quintana Roo, Campeche, and Chiapas constitute the primary forest region of the country. Their trees, which are hardwood, are used in furniture making and other industries. The sapodilla should be mentioned for the importance of its latex as a raw material from which chicle is made. Mexico is the world's leading exporter of chicle, of which 1,801,737 kilograms, valued at 23,130,044 pesos, were produced in 1951.

These forests are subjected to an immoderate exploitation, but their exuberant growth facilitates natural reforestation.

(3) Tropical humid climate, with rainfall in summer (Aw), in the coastal plain of Veracruz, the north of the Yucatán Peninsula, the Pacific coastal plain from central Sinaloa to Chiapas, part of the Balsas Depression, and the central depression of Chiapas. Vegetation is of the tropical savannah-type grassland, consisting chiefly of herbaceous plants, among which may be mentioned amaranth, jicama, gourds, pineapples, and bananas.

(4) Dry climates, steppe (BS) and desert (BW), are found in the northern stretches of the Central Plateau, in the plains of Sonora and Sinaloa, the Peninsula of Lower California, in a strip all along the western side of the Sierra Madre Oriental, and in the extreme northwest of Yucatán. In all these regions the steppe climate surrounds the desert.

There is also a type of steppe vegetation on the plateaus that extend from San Luis Potosí through eastern Puebla as far as the central plateaus of Oaxaca, as well as in the lowest part of the Balsas Depression and in other depressions, such as that of Lake Cuitzeo.

The steppe vegetation is grass and drought-resistant plants, whereas the desert has only drought-resistant plants or naked sands and rocks. Among the most important types of drought-resistant plants are cacti, agave, yucca, mesquite, candelilla, and guayule.

(5) Temperate humid climate with rains in winter (Cs) is characteristic of the northwest region of the Peninsula of Lower California. The vegetation here is either grassland or prairie (see classification 8).

(6) Temperate humid climate with rains throughout the year (Cf) occurs in the upper reaches of the sierras, and is characterized by coniferous forests.

These forests are formed chiefly of gymnospermous conifers, of which the most important are pines, oyamel (*Abies religiosa*), *abeto,* the common juniper, and the ahuehuete (*Taxodium mucronatum*). These softwood trees are found in the San Pedro Mártir and Juárez sierras in northern Lower California, in the Sierra Madre Occidental, the Sierra Madre Oriental, the Sierra Volcánica Transversal, in the highest regions of the Sierra Madre del Sur, and in the Sierra Madre de Chiapas. Being found the length of the country and being located near centers of population, they are exploited on a national scale. They supply wood for building and furniture, as well as wood pulp and resins used by medicine and industry, such as pitch and turpentine. The coniferous forests have been subjected to an immoderate exploitation, but are protected to a certain extent by their location in the mountains. The exploitation of pine represents about three quarters of the forest production of the country.

(7) Temperate humid climate with scant rainfall in all seasons (Cx') is found only in northern Tamaulipas and in some mountainous areas of Nuevo León and Coahuila. Steppe vegetation prevails (see classification 4).

(8) Temperate humid climate with rainfall in summer (Cw) occurs on the western slope of the Sierra Madre Occidental, in the southern valleys of the Central Plateau, in the Sierra Madre del Sur, the Sierra Madre de Chiapas, and in the northern mountainous region of the latter state. Vegetation is prairie grassland. The vegetation of the temperate humid prairies is formed chiefly of grasses, among the most important of which are epazote (*Chenopodium ambrosioides*), zacaton (*Epicampes macroura*), and otate (*Gradua amplexifolia*).

(9) Polar climate due to altitude (EB) is found in the higher elevations of some mountains. This classification has two subtypes: (ET) tundra vegetation, consisting of lichens and bunch grasses, is found on the Nevado de Colima, Nevado de Toluca, Cofre de Perote, and Malinche, as well as at corresponding elevations on the still higher volcanoes; the climate of perpetual ice (EF) occurs in the most elevated regions of Citlaltepetl, Popocatepetl, and Ixtaccihuatl.

Mixed Forest of Temperate Regions.—This type of forest is characterized by dicotyledonous angiosperms and gymnospermous conifers; thus, besides the conifers, there are live oaks, oaks, willows, and ash and walnut trees, among others. The mixed forests are found on the western slope of the Sierra Madre Occidental, southern slope of the Sierra Volcánica Transversal, northern slope of the Sierra Septentrional de Chiapas, and the eastern slopes of the northern and southern parts of the Sierra Madre de Chiapas.

The mixed forests, like the forests of softwood conifers (classification 6, above), are thus found the length of the country, and are exploited on a national scale. Since many of the mixed forests extend into the southern valleys of the Central Plateau, however, they have suffered a more severe exploitation than have the coniferous forests. Live oaks, oaks, and walnut trees are used chiefly in furniture making; pines, for building, furniture, and to obtain resins.

Fauna.—The animals belong to the two great

zoogeographical regions of the American continent, the Nearctic and the Neotropical, since the boundary between the two is in Mexico. This boundary crosses the Gulf and Pacific coastal plains roughly at the Tropic of Cancer, but altitude then forces it southward along the Sierra Madre Oriental in the east and the Sierra Madre Occidental in the west until it reaches the Sierre Volcánica Transversal, where it crosses the interior of the country in an east-west direction. North of this boundary the fauna is almost exclusively Nearctic (of the Rocky Mountain subregion); south of it the fauna is neotropical.

Among Nearctic mammals are the wild sheep, pronghorn, and several species of deer and bear; among Nearctic mammals with Neotropical components are the tapir, puma, jaguar, and various deer. Neotropical mammals include marsupials, such as the opossum, and those of the American type, such as the armadillo and monkeys.

2. POLITICAL DIVISIONS AND POPULATION. The initial political division of Mexico, similar to the present division, was incorporated in the federal Constitution of Oct. 4, 1824, which divided the federation into 19 states and 4 territories, and adopted the federal popular representative form of government. The states included Texas; the territories, Upper California and New Mexico (Santa Fe). These two territories, as well as Texas—whose declaration of independence in 1836 was not recognized by Mexico—and parts of the states of Coahuila, Chihuahua, and Sonora, were ceded to the United States in the treaties of Guadalupe Hidalgo in 1848 and Mesilla (Gadsden Purchase) in 1853. The territorial extension of Mexico before these treaties was approximately 1,544,400 square miles; hence it is now less than half what it was during the colonial period and the first years of independence.

Under the Constitution of 1857 the republic was reorganized into 24 states and 1 territory. The constitution promulgated Feb. 5, 1917 recognized 28 states, 3 territories, and the Federal District, which corresponds to the District of Columbia in the United States. The admission of the Territory of Northern Lower California as a state on Jan. 16, 1952, however, changed the organization of Mexico to 29 states, 2 territories (Southern Lower California and Quintana Roo), and the Federal District, which are tabulated on the accompanying table, with their respective areas, capitals, and populations according to the census of 1950. The states and territories are divided into *municipios* (municipalities), of which there were 2,349 in 1950. The Federal Dis-

[1] Preliminary report dated March 24, 1953. [2] Preliminary report. [3] Does not include uninhabited islands (2,224 square miles) or continental shelf (154,633 square miles). [4] National average.

trict, which includes Mexico City, the national capital, is divided into 12 delegations.

Population.—Mexico completed its seventh general census, by modern techniques, on June 6, 1950. This showed a population increase of 30.8 per cent over the 1940 figure of 19,653,552. The areas in which this increase was the greatest during these 10 years were Northern Lower California (187.5 per cent), the Federal District (73.5 per cent), Tamaulipas (56.3 per cent), and Morelos (49.4 per cent).

The crude birth rate in 1950 was 45.79 per 1,000 inhabitants and the crude death rate was 16.1 per 1,000, both among the highest in the world. The death rate, however, had been reduced from 26.1 per 1,000 in 1921 and 24.4 per 1,000 in 1937. The growth of population is about half a million persons per year. For the economic effects of this growth see the section *Economic, Industrial, Agricultural, and Financial Factors* (Population).

Chief Cities.—The urban population of Mexico numbered 10,983,483 in 1950, or 42.59 per cent of the total. The census showed 10 cities of more than 100,000 inhabitants; in contrast to the censuses of 1930 and 1940 in which only Mexico City, Guadalajara, Monterrey, and Puebla exceeded that figure. All these 10 cities were capitals (shown on the accompanying table), except Torreón (128,548), Ciudad Juárez (122,598), and León (122,585).

3. RACIAL COMPOSITION, POPULATION TRENDS, AND HEALTH. Mexico ranks among the most populous of those Latin American countries with a mixed racial origin. Mestizo (mixed) elements make up the preponderant part of the population, but a large part of this population is Indian.

Indians.—The criteria which have served to characterize the Indians as such are very diverse, since the problem of defining what is Indian is not easily solved. Alfonso Caso, in "Definición del indio y de lo indio" (see *Bibliography*), says:

> An Indian is one who feels that he belongs to an Indian community; an Indian community is one in which non-European physical elements predominate, which speaks an Indian language by preference, which possesses a large proportion of Indian elements in its material and spiritual culture, and which, finally, has a social sense of being an isolated community among the communities which surround it, which makes it distinguish itself both from white and mestizo groups.

The foregoing definition, of a practical nature (above all for the end of applying social and economic measures), is very far from what might be expected as a biological definition. Nevertheless, the statistician is more interested in knowing whether a population group lives in accordance with the characteristics of Indian culture than whether that group possesses the physical and psychic traits corresponding to a given race. Furthermore, after the many contacts which have taken place in the past, not only in the Mexican population but over the entire globe, it is useless to continue insisting on pure races.

For many years the linguistic criterion was the only one considered valid for purposes of the census. This was criticized by anthropologists like Manuel Gamio, and beginning with 1940 later censuses took into account not only language but the presence of other cultural traits, which bring students of these statistics closer to reality. Theoretically, perhaps, it might be thought that biological data would be the only sure data for classification, but this is invalidated by racial mixture. Therefore, although as was stated above, Caso's concept seems to clash with the scientific rigor of physical anthropology, it is the only one valid for the social ends aimed at.

Within the same Indian group, classified as such because of language, can be found the physical variations which are precisely those which make classifications difficult. A typical example, among many others, is provided by the Trique Indians of the Mixtec area, in the State of Oaxaca; those living in the mountains differ completely from those along the coast as regards physical characteristics, and even psychic ones, and yet they are grouped together because they speak the same language.

The classification of the Indian population from the point of view of physical anthropology has been only slightly satisfactory because it has not always been possible to collect a sufficient amount of data, evaluated statistically. Nevertheless, the available statistical material does permit an overall picture adequate for forming a criterion with respect to that mosaic of native races and languages which constitutes the modern Mexican people. There is a series of coincident facts which are easily perceived, without going into details. The Indian tribes of high physical stature are found in the northwest of Mexico, and as one goes southeast they become smaller in stature. In general, this seems also to hold true for head shapes (cephalic index), since the most brachycephalous (short-headed) groups are found in the southeast, and the most dolichocephalous (long-headed) groups in the northwest. There are, however, clear exceptions to this.

Pre-Hispanic Population.—It has been noted that the Indian part of the population forms a large demographic nucleus. Since the present-day Mexican has developed from Indian roots, what is known of the Indians' origin, distribution, and principal differentiating characteristics must now be treated.

It is agreed among most anthropologists that the first inhabitants of Mexico, as of the Americas in general, were predominantly of Asiatic origin. An eclectic theory of the populating of the Americas admits both the arrival of migrations by way of the Bering Strait and sporadic influences from Polynesia. The precise date of arrival has not been agreed upon, but dates ranging from 10,000 to 25,000 years ago have been suggested. The discovery, in 1952 at Santa Isabel Ixtapan, State of Mexico, of the skeleton of a mammoth (*Archidiskon imperator*) of the Pleistocene period associated with projectile points and scrapers indicates that in this epoch the Valley of Mexico was already populated by hunters.

It is interesting to note that a high percentage of the modern Indian population is medium-headed (mesocephalic) or brachycephalous, and that the places where the bones of dolichocephal-

alous Indians have been found are sites which have been long uninhabited, as, for example, those of the Pericu Indians of the southernmost part of the Peninsula of Lower California. The present-day Indians with tendencies toward longheadedness are likewise found in marginal areas. This has been interpreted as indicating that longheads formed the first migratory waves and were displaced by shortheaded peoples and forced into less favorable regions. Much has been said of such migratory waves and there is much difference of opinion among the various authors.

In general, the hunting, fishing, and gathering groups of pre-Hispanic Mexico occupied the north, where environmental conditions are less favorable for the evolution of more complex cultures. On the other hand, the areas which anthropologists have named Meso-America (central and southern Mexico, British Honduras, Guatemala, western Honduras, and El Salvador) saw the flourishing of a whole series of peoples whose cultural manifestations have surprised modern man.

The question of what influence the environmental conditions may have had on the physical aspect and method of reacting of the diverse inhabitants of the Mexican territory has not been investigated, perhaps because of the complications which would arise, but it is easy to deduce that the people who reached the Central Plateau from the north did so in large measure under the pressure of the scarcity of means for supporting life. Nomadic tribes, with an economy based on hunting and gathering, suffered great privations in the mountains and deserts of the north. The climate in this region is very extreme, and such living conditions were surely a sufficient stimulus for them to venture southward. Once in less inclement territory, with abundant food and better possibilities for supporting life, they must have changed from a widespread nomadic existence to one close to a sedentary mode.

Later, when agriculture had satisfied their basic needs, they could begin to create all that series of cultural accomplishments whose remains we admire. It is clear that the same impulse which guided the first inhabitants of the plateau stimulated subsequent waves and was the origin of conquests and reconquests by the many peoples of whom archaeologists and historians speak. This was the panorama through which passed Chichimecs of different origin, Toltecs, Mayas, Mixtecs, Zapotecs, Tarascans, Aztecs, and others. These constant clashes always brought as a consequence more or less permanent contacts which resulted in group mixture, with a natural interchange of customs, language, myths, techniques, and what interests us here, biological mixture. Mixture certainly caused many of the variations we observe, but it is also certain that the environment acted on them, leaving more or less permanent characteristics.

There was much less movement from south to north. In the majority of cases it consisted of readjustments, or of changes sought by centers of population already established, whose commerce and highly evolved population required slaves and artisans. It is natural that good living conditions should permit an increase of population, either through a high birth rate or by the immigration of subjugated groups.

Centers of Concentration.—Upon their arrival, the Spaniards found an extensive territory, very unevenly populated. In some areas there was a large concentration of population—responsible chroniclers are of the opinion that the great Tenochtitlan (on the site of Mexico City) had no less than 60,000 houses, which is to say about 300,000 inhabitants, and in addition a series of widespread tributary towns.

The metropolis was the seat of the dominant group, the Aztecs, whose hegemony extended southward to modern Central America. In the northwest its power did not extend as far, reaching only to the borders of Michoacán. Beyond this point there are only records of a multitude of seminomadic or completely nomadic tribes, of whose customs and languages we have information, but whose numbers it is difficult to calculate.

The major concentration of population at the time of the Spanish conquest was thus located in the plateau. Perhaps in earlier times the coast and the tropical plains had had the greatest population, since the ruins in the Maya zone bespeak very large concentrations in those regions. Only the presence of hundreds of thousands of workers can explain the building of the huge edifices which were already in ruins upon the arrival of Europeans in Mexico.

Teotihuacán, with its enormous pyramids and its area of some 11 square miles with abundant remains of dwellings, must have been another great center of population, but its inhabitants were dispersed long before the conquest, perhaps by the push of tribes which were barbarian but full of combative vigor. The same fate overtook other large centers of population such as Monte Albán, Tula (Tollan), and Xochicalco.

Of all these, the only ones remaining upon the arrival of Hernán Cortés (Hernando Cortez) were the urban centers of the Valley of Mexico, seats of the great chiefs who with Montezuma (Moctezuma) formed the triple alliance of the cities of Tlacopan, Texcoco (or Tetzcoco), and Tenochtitlan, with Tlatelolco only recently dominated. We have sufficient information on the Aztecs to substantiate their flourishing civilization. That their population was constantly increasing is proven by the need of the Aztecs for expansion, notwithstanding the fact that war and other calamities must have reduced their numbers very frequently.

Outside the Aztec Empire perhaps the major center of population was Tlaxcala, for which a population of about 500,000 has been calculated for that period. The Tarascans in Michoacán formed another nucleus of demographic importance.

Precise data are lacking with respect to the total population on the eve of the conquest. Each of the investigators, like their informants, makes personal appraisals that do not resist analysis. According to the historian Gonzalo Aquirre Beltrán, the one that is perhaps closest to reality is Angel Rosenblat, who after a careful analysis estimates that 4.5 million Indians were living in the territory that now forms Mexico in 1519, the year the Spaniards reached Tenochtitlan.

Conquest and Colony.—In 1570 the Indian population diminished to 3,366,860, and in 1646, according to Aguirre Beltrán, it dropped to only 1,269,607. This tremendous decline has been variously explained. In Tenochtitlan alone, the war which decimated more than one third of the population was a tremendous depopulating factor at the beginning of the conquest. Not only did the conquest cause death directly, but it

dispersed many groups which, not being able to adapt themselves to new conditions of life, thus perished. In addition, contacts with sick Europeans and Negroes, helped by the exhaustion due to fatigue and inadequate nourishment, let loose truly catastrophic epidemics, such as those of smallpox in 1520, measles in 1529, and typhus in 1545, which took millions of lives. Gilberto Loyo cites the fact that some 2 million Indians died of matlazahuatl (Mexican typhus or tabardillo) between 1573 and 1577. The inhuman exploitation to which the Indians were subjected, the change in their way of life, their removal to different zones, and so forth, were other factors which explain the decrease in population suffered in the first periods of the conquest. The European and Negro populations may be considered still insignificant, but mestizos and *Criollos* (native-born whites) began to multiply rapidly.

The paternalistic laws for the protection of the Indians, in spite of their remaining dead letters in large part, gave rise to a situation of social as well as demographic importance. In an attempt to free the Indians from the exhausting labor to which they were subjected in the mines and in the cultivation of sugar cane, and so forth, permission was obtained in 1501 to bring Negro slaves to the Spanish colonies. In Mexico most of these were settled in the hot lands of Veracruz and Guerrero; still others were taken to the mines in Zacatecas.

Aguirre Beltrán gives the population figures in the accompanying table (the terms Euro-, Afro-, and Indo- indicate mixtures in which European, African, or Indian characteristics predominated in the mestizos).

Year	Spaniards and *Criollos*	Negroes	Indians	Euro-mestizos	Afro-mestizos	Indo-mestizos	Total
1570	6,644	20,569	3,366,860	11,067	2,437	2,435	3,410,012
1646	13,780	35,089	1,269,607	168,568	116,529	109,042	1,712,615

Social Structure.—The Negroes, with the Indians, formed the lowest stratum of colonial society, and their conditions of misery were the motive for the constant unrest manifested through mutinies and rebellions. From the mixtures among them arose the so-called castes. The word "caste," eminently biological, was given a derogatory meaning in the colonial period, comprising not so much the physical characteristics of the individuals as their social extraction, without forgetting their racial mixture. The attempt to define precisely the last degree of difference between such mixtures, as the various combinations passed through generation after generation, gave rise to terms which were ridiculously elaborate and often artificial.

The mestizos, who in the beginning had been well regarded—to the extent that some were admitted into the Spanish nobility—were relegated to a secondary status as they grew in numbers. They were considered quarrelsome individuals, and they, for their part, feeling themselves humiliated by the whites, showed their resentment in violent form. On the other hand, the mestizos looked down on the Indians for having been conquered, thus showing themselves to be what they were, unadapted beings who participated in the social environment only with difficulty.

The native-born whites, or *Criollos,* comprising a class which could have been the elite, since they had on their side all the privileges of its racial and economic condition, felt neglected before the hierarchical superiority of the Spaniards, to whom the crown entrusted the official duties.

This accumulation of circumstances unfavorable to the harmony and progress of colonial society was the leaven which, after receiving an incentive from the ideas of revolutionary France, brought on the struggle for independence.

The nucleus of white Spaniards was never numerous—only 7,904 individuals in 1793, from which it may be inferred that only a few thousand men had control of the political, judicial, military, and ecclesiastical functions, and like positions. The decline of the Indian population had finally ceased about this time and a slight increase had begun. The mestizos and mulattos were also increasing in numbers. In a total population of 3,799,561 in 1793, it is calculated that 61.1 per cent were Indians and 38.6 per cent were mestizos and mulattos; of the remainder, 0.2 per cent were Spaniards and *Criollos* and 0.1 per cent were Negroes.

Later Population Trends.—The struggle for independence (1810–1821), like all wars, brought about a series of upheavals, as well as a slight decrease in population. Soon, however, there occurred a readjustment favorable to population gains.

In conclusion it may be said that the present population of Mexico is predominantly mestizo, and that a large proportion, 20 to 25 per cent of the total population, has Indian cultural characteristics. The Indian population has been growing, although from the linguistic point of view the great majority are interested in learning Spanish in addition to their mother language and in adopting various elements of Western culture. Since the Revolution of 1910 various programs have been undertaken to provide them with lands and with economic and cultural media, to achieve the homogenization of the population.

Indian Health and Diet.—Various circumstances have influenced the disappearance of innumerable Indian groups, above all in northern Mexico, but in those places occupied by individuals who had reached a sufficiently advanced state of cultural evolution, the Indian was able to resist all that man and nature brought against him. In addition, the conquerors and the other white rulers who followed them through time, knew that land without someone to work it lacks value —from an economic point of view, the Indians were one with the land, a most valuable factor which had to be conserved. Hacienda owners bought their land making sure that with it went a sufficient number of laborers to exploit it.

Thousands of these laborers, principally members of the rural population, have continued to live in very precarious hygienic conditions. Water-borne diseases cause very serious disorders among them, weakening them physically. It is certain, however, that little by little they have become naturally immunized against the diseases brought by Europeans and Africans. There

were no returns of the great epidemics like those of the 16th century mentioned above. Nevertheless there still remain wide areas in which malaria, tuberculosis, and parasitic diseases continue to reduce their numbers. Some maladies have thrived specifically among the Indians, such as onchocerciasis, which occurs in an extensive zone of Chiapas, and pinta in Guerrero, Morelos, Michoacán, and other states.

It has been said that the Indian diet is inadequate and poor in nutrition, and that their feeble resistance to disease results from this. Such an assertion is in general false, since besides the fact that the Indian is not especially susceptible to disease, various other causes may have unfavorable effects on his resistance. The Indian diet may not include a series of foods which are considered basic in the diet of Western civilization, such as milk, eggs, and meat, but the nutritive content of such products is supplied by other foods containing the necessary factors. The basic Indian diet is composed of corn (maize), beans, and chili peppers, and in the highlands, pulque, a drink extracted from agave plants. This diet is supplemented with a series of vegetable and animal products which vary according to the region. Even in extremely poor regions, such as the Mezquital Valley inhabited by Otomí Indians, where the basic foods are corn, chilies, and pulque, the Indians have found additional foods, such as insects, larvae (including the grubs found on maguey plants, and caterpillars), and other animal products, which with beans, mesquite, and fresh vegetables complement their diet so that sicknesses due to nutritional deficiencies are not encountered among them.

NATIONAL HEALTH

The death rates of a population are one of the best expressions of its state of health, since it is to be expected that a decline in death rate indicates a reasonable adaptation of sanitation and technical control to factors of climate and social conditions.

Mortality Rates.—The Mexican death rate has experienced a constant decline during the decades after 1930, when it was 26.6 per thousand inhabitants, but in spite of this fact it must still be considered high in comparison with other countries. The average death rate during the years 1941–1945 was 21.5 per thousand inhabitants, and it declined to 17.4 in the following five years, 1946–1950 (see Table 1). Assuming that registration in the less populated areas was complete, the average mortality during the latter period was lower in rural (16.0) than in urban surroundings (20.9).

The death rates are highest in the Central Region,[1] a fact that would indicate that the most densely populated area and cultural center of Mexico presents a greater sanitary problem than other regions in the notably hazardous tropics. Only two states of the Central Region, Jalisco and Michoacán (16.4 and 16.9), present rates slightly below the national average, and three of them, Mexico, Puebla, and Tlaxcala (23.2, 23.5, and 24.3) have the highest mortality rates in the country. With the exception of Northern Lower California (17.5) in the North Pacific Region, and Colima and Oaxaca (17.9 and 21.7) in the South Pacific Region, the death rates in the states of the other four regions were lower than the national average for the period 1946–1950.

Infant Mortality Rates.—Infant mortality plays an important role in the high general death rate. Although it too has been declining, it is still very high; 29.4 per cent of the total number of deaths during 1950 were due to deaths of children under the age of one year. The average infant death rate for 1946–1950 shows that one out of every ten children born alive dies before it reaches the age of one year (see Table 2). Again, it is in the Central Region that we find by far the highest infant mortality rates. The Federal District (134.4) and the states of Mexico (145.5) and Tlaxcala (146.8) included in this region had the highest rates in the whole country in 1946–1950.

Causes of Death.—In Table 3 the principal causes of death are arranged according to the number of deaths per 10,000 inhabitants. The three causes most disastrous to Mexico are diarrhea and enteritis, pneumonia, and malaria.

The decline in the number of deaths caused by diarrhea and enteritis, as well as by dysentery, typhoid and paratyphoid fever, can only be attributed to better general sanitary conditions, such as improved water supply and drainage, greater hygiene in the food supply, and to education and other factors.

The high number of deaths caused by pneumonia is due principally to inadequate housing conditions and clothing. In spite of the hope offered by the use of sulfa drugs and antibiotics, mortality declined only slightly and has tended to remain more or less the same.

The high death rate from malaria is due, on the one hand, to special environmental conditions, and on the other, to the lack of adequate communications, the poverty, and the low standard of hygienic education characteristic of the *tierra caliente* (hot country) where malaria is endemic, that is, the southern part of Mexico and along the Pacific and Gulf coasts.

A serious problem is presented by the considerable isolation of the majority of Mexico's rural population and a shortage of physicians who are willing to sacrifice comfort and to live among people often opposed to their services because of their nonscientific conception of the causes of disease. According to the census of 1940, only 8.7 per cent of physicians were practicing in rural areas, which contain 57.4 per cent of the total population. In order to solve this problem, the federal government in 1936 organized a bureau now known as the Dirección General de Servicios Médicos Rurales Cooperativos, and every medical student is obliged to practice his profession in some rural area during five

4. THE INDIAN GROUPS. These groups still form an important part of Mexico's population. The area of present-day distribution of Indian groups which, to a greater or lesser degree, maintain their ethnic characteristics and group consciousness, coincides generally with the areas inhabited by sedentary peoples in pre-Hispanic times. These are central and southern Mexico and a strip in the northwest along the Pacific coast and the Gulf of California (in Sinaloa and Sonora) and the Sierra Madre Occidental. It was there that "the settled Indian was fitted into the colonial and modern economic scheme, in fact this was built upon him" (Alfred L. Kroeber, *Cultural and Natural Areas of Native North America,* University of California Press, 1939). There is a rough correlation between the pre-Hispanic density of population and cultural development, and the strength of Indian groups today.

The Indian groups may be defined on the basis of the following characteristics: (1) they are composed of individuals who are predominantly Indian from the physical point of view; (2) they possess group consciousness (they consider themselves Indian), and are considered Indians by outsiders; (3) with but few exceptions, they speak Indian languages; (4) in differing degrees they maintain in their cultures a larger proportion of pre-Hispanic or preindustrial elements than the proportion of these elements in the national (or modern Mexican) culture. The persistence of pre-Hispanic and preindustrial elements of culture is especially evident in technology and economy.

As regards point 1, there is some degree of *mestizaje* (white and Negro admixture) in most Indian groups. Nevertheless, in Mexico, cultural differences are vastly more important in the characterization of Indian groups than racial differences. The Indian who abandons his Indian mother tongue and becomes assimilated to modern Mexican culture becomes a Mexican, and is socially accepted as one. In some areas, such as the Isthmus of Tehuantepec and the Mixtec area, the use of group names (*tehuano, mixteco*) to designate specific ethnic groups is being lost. The tendency is to use these terms as regional names, regardless of racial and cultural origins.

With regard to point 4, several centuries of colonial rule and, more recently, the impact of Western industrial civilization have modified the Indian cultures to a varying extent. It is impossible to generalize about the degree of assimilation of Indian groups to modern Mexican culture.

Socially, the Indian groups form rural communities which are generally subordinate to the

[1] For a listing of the states comprising these regions, see *Political Divisions and Population.*

semiurban or urban Ladino groups; the latter consisting of individuals who speak Spanish and participate in modern Mexican culture. Racially, the Ladinos are very mixed, with a considerable proportion of white admixture. However, the distinction is cultural rather than racial, and there are possibilities of passage from Indian to Ladino, through cultural and social changes. In some areas, the relationship between Indian groups and Ladinos comes close to being a caste system—for example, in Chiapas. In other areas this relationship is rather that of a class system. This seems to depend on the different economic development of the various regions. Some Indian groups, such as the Maya in the Quintana Roo forests, the Lacandon in the Chiapas jungle, the Huichol in the mountains of Nayarit, the Tarahumara (or Tarahumare) in the mountains of western Chihuahua, live in isolation, without maintaining relationship with Ladinos.

Linguistic Divisions.—The only general criterion which permits a statistical evaluation of the importance of the Indian groups in modern Mexico is the linguistic one. According to the 1940 census there were 1,237,018 individuals more than five years old who spoke only Indian languages (monolinguals), and 1,253,891 individuals more than five years of age who were bilinguals or plurilinguals, speaking Spanish as well as one or more native languages. The total number (2,490,909) of monolinguals and bilinguals more than five years old represented 15 per cent of the total population in that age category. The corresponding figures from the 1950 census showed 795,069 monolinguals and 1,652,540 bilinguals, or a total of 2,447,609, a considerable reduction in view of the fact that the total population of Mexico increased some 30 per cent during the decade.

Taking the Indian population by groups, the most important is made up of the people who speak Nahuatl, the language of the Aztecs (355,295 monolinguals; 360,071 bilinguals; total: 715,366), and live in the states of Puebla, Veracruz, Hidalgo, Morelos, Guerrero, and in the Federal District. All the figures refer to the population more than five years of age, in 1940. There follow, in order of importance: Maya (131,836 monolinguals; 114,011 bilinguals; total 245,847), in Yucatán, Campeche, and Quintana Roo (see also the article MAYA); Mixtec (111,391; 124,994; total 236,385), in Oaxaca and the adjacent zone of Guerrero; Zapotec (111,660; 104,661; total 216,321), in Oaxaca; Otomí (94,693; 87,404; total 182,097), in Hidalgo and the State of Mexico; Totonac (58,561; 59,242; total 117,803), in Veracruz and Puebla; Mazatec (45,254; 55,743; total 100,997), in Oaxaca and Puebla.

Among the groups smaller than 100,000 we find the Tzotzil (75,207, total of monolinguals and bilinguals) in Chiapas; Mazahua (68,855) in the State of Mexico; Tzeltal (66,861) in Chiapas; Mixe (51,261) in Oaxaca; Huastec, or Huaxtec (46,631) in Veracruz and San Luis Potosí; Chinantec (37,577) in Oaxaca; Tarascan (34,880) in Michoacán; Chol (34,624) in Chiapas; Tlapanec (27,698) in Guerrero; Tarahumara (26,007) in Chihuahua; Chatino (16,794) in Oaxaca; Zoque (15,732) in Chiapas and Oaxaca; Amuzgo, or Amishgo (13,219) in Guerrero and Oaxaca; Mayo (12,831) in Sonora and Sinaloa; Tojolabal (11,653) in Chiapas; Cuicatec (10,005) in Oaxaca. There also exist many groups of less than 10,000 individuals.

5. THE WAY OF LIFE. Modern Mexican life presents a complex of striking contrasts: Parisian fashions alongside Aztec mantles; Coca-Cola and the thousand-year-old nectar of the gods, pulque; the baseball field and the bull ring; and most significant, minds molded in ancient ritualistic patterns mastering 20th-century machine tools. As in the Far East, the new has met with the old, the European with the native. A clash was inevitable, and the results—economic, political, and social—are only now taking definitive form.

Food and Drink.—In Aztec times the basic diet consisted of corn (maize), beans, and chili. Corn was prepared in an infinite variety of ways, the most popular being the *tortilla,* a thin, flat, unleavened bread. Tamales (corn dough steamed in corn husks) and the less well-known *pozole* (corn soup) were common fare. The ancient Mexicans supplemented their diet with turkeys, boars, rabbits, fowl, and a great variety of fruits, herbs, and insects. All these foods have retained their importance and still may be said to constitute the main diet of the Indian population. Cattle, wheat, and certain fruits such as oranges, apples, and grapes were perhaps the most significant European contributions.

Following the Spanish tradition, the main meals are the *desayuno* (breakfast), the *comida* (a large meal of several courses served about two o'clock in the afternoon), and the *merienda* (a very light supper at eight or nine in the evening). In the large cities this customary eating pattern has changed somewhat during this century. Many of the middle class now favor a lunch at midday, as in the United States, and a heavier *cena* (supper) in the evening.

The most popular drink of the Indians is pulque, the fermented juice of the maguey, a cactus plant. Its alcoholic content is slight. More potent than pulque are tequila and mezcal, also derived from the maguey. The excellent beers of the European type brewed at Monterrey, Nuevo León, in the north, and at Orizaba, Veracruz, near the east coast, are extremely popular throughout the republic and have replaced pulque to a considerable extent.

Dress.—In pre-Hispanic times among the majority of the Indian population, dress was extremely simple. Men usually wore a loincloth, sandals, and a cotton mantle (the Aztec *tilma*) draped and tied over the right shoulder. A long cotton blouse and a skirt held to the waist by a

sash constituted the general female attire. The Spanish manner of dressing changed male clothing habits radically: the natives of most rural districts are now to be seen wearing white cotton trousers, a shirt, and inevitably, a straw hat. Except in the warmest areas, they will usually be seen wearing or carrying a serape (or *sarape*), a woolen blanket whose design and colors vary from region to region. This is perhaps the only Aztec remnant in male attire, and stems from both the ancient cotton *tilma* and the Spanish capote, or cape. The women of some Indian groups may still be seen dressed in the ancient, pre-Hispanic blouse and skirt. Statistics reveal that approximately one half of the population has not adopted shoes of the European type.

In the cities the average well-to-do or middle-class Mexican wears very much the same clothing as is worn in the United States or Europe. A certain amount of formality, not so often seen in the United States, is noticeable among the men; materials are darker as a rule, tailoring is conservative, and sports clothes are not as commonly accepted. Hats are seldom worn by women, and on those rare occasions when head covering is in order, the *rebozo* (shawl), the veil, and the Spanish mantilla are the most common forms of headgear among all social classes. A revival of interest in folk costumes has taken place since about 1940. The decorative *rebozo*, as an article of high fashion, has come into its own. *Huaraches*, the attractive native sandals, have become increasingly popular for resort wear among the Mexicans.

Sports.—The traditional spectacle and main source of hero worship in Mexican life, bullfighting, has continued to maintain its popular appeal. Nevertheless, some *toreo* impresarios and enthusiasts lament the fact that the new generation is turning more and more to football (which in the United States would be called soccer), basketball, and baseball as recreational outlets. The decades after 1920 witnessed an ever-increasing interest in these athletic "imports." Contrary to the general trend in the United States, the emphasis in Mexican sports is primarily on the amateur and the spontaneous. In the larger cities a Sunday morning finds thousands engaging personally in ball games; even the most primitive native villages generally can boast an open-air field, equipped at least for basketball.

A growing rivalry, sportswise, between the various colleges has created a demand for better playing fields and more adequate spectator accommodations. The Olympic Stadium of the Universidad Nacional easily seats 100,000 persons. Radical in design, this great elliptical bowl is the sports center of the capital's ultramodern University City, which was dedicated in 1952.

On the professional level, *frontón* (or *jai-alai*), a court game of Basque origin, maintains an almost fanatical following. Betting is an integral part of the game and fortunes can be made—or lost—nightly at the Frontón México in Mexico City.

Fiestas.—The great Christian festivals are still celebrated with considerable liturgical pomp, attracting enormous crowds of the devout to churches and shrines. Household celebrations of these same feasts are often occasions for informal gatherings. One of the foremost among these great holy days is *Los Santos Reyes* ("The Holy Kings," that is Epiphany, or the feast of the Wise Men). On this day, January 6, children receive their gifts from the Three Kings of the East; the Santa Claus tradition is unknown except among the city sophisticates. *Semana Mayor* (Holy Week) inspires a truly popular outburst of religious fervor. A number of Indian communities have become famous for their Passion plays and public processions on Friday of this week.

The most significant Aztec religious festival, the feast of the offerings to the spirits of the dead, oddly enough coincided with the remembrance of the faithful departed in the Catholic calendar (November 2). Many pagan practices persist to this time: special household altars are prepared and covered with curious ceremonial breads (*pan de muerto*), meat dishes, *tortillas*, cigarettes, toys, and other articles to placate the dead.

December 12 finds hundreds of thousands of Mexicans, particularly the Indians, converging on Mexico City and thronging the great basilica of the Virgin of Guadalupe, patroness of the republic, which is north of the city.

The nine days preceding Christmas represent the happiest and most carefree of the religious year. *Posadas* (literally "inns"), representing the journey of Mary and Joseph to Bethlehem and their search for an inn, are enacted nightly in many homes. In more recent years these celebrations have taken on a more frivolous tone, and cocktails and dancing have come to be expected.

Regional Differences.—These, as they are found today, are direct or indirect results of the colonial policies followed by the conquerors during the three centuries of Spanish hegemony.

In the southern part of Mexico the European colonizers encountered flourishing centers of native culture, such as the Aztec, Maya, and Zapotec confederations. Sedentary in nature, these ethnic groups tilled the land, consolidated their political positions, and had reached a high point of refinement in the arts and sciences. While many of their political, social, and religious institutions suffered an almost total eclipse with the conquest, the basic patterns of folk culture persisted and came to constitute an integral component of the Hispanic-Mexican civilization. With these groups the Spanish crown accepted and even encouraged intermarriage, which resulted in the emergence of the mestizo (mixed) population.

On the other hand, in the northern desert stretches the Spanish settlers found only barbarous, nomadic tribes. Agricultural stability was virtually unknown, and life was devoted to hunting, fishing, foraging, and intertribal warfare. In a word, the culture pattern of this region was strikingly similar to that prevailing among the Indians in United States territory. As often happens with such marginal and submarginal groups, contact with the European resulted either in the annihilation or cultural ineffectiveness of the native. At the present time, tribes such as the Tarahumara of Chihuahua and the Yaqui of Sonora roam the plains and mountain ranges exactly as they have in centuries past; the Indian reservation is an institution unknown to the Mexican people. These fiercely independent tribes take little part in civic activity, and numerically constitute an almost negligible part of the modern population.

European stock, therefore, has remained rel-

atively pure in northern Mexico. This in turn has facilitated the assimilation of ideas, customs, and attitudes from the United States. Such has not been the case in certain southern states, such as Oaxaca, Puebla, Guerrero, Tlaxcala, and Chiapas.

While inhabitants of both regions possess a deep-rooted consciousness of national spirit, the southern mestizos and Indians tend to regard the *norteños* (northerners) as more frank, thrifty, businesslike, and self-assertive, though too "Americanized" in their language, manners, and general way of life. Mexicans of the north, particularly in Sonora, Chihuahua, Coahuila, and Nuevo León, find it difficult to accept their southern neighbors' Indian ceremoniousness, passivity, and general fatalistic attitude. Mexico City is a case in itself, with an atmosphere all its own. Here, Indian currents and those from Europe and the United States have found a meeting place, contributing to the formation of a complex, cosmopolitan way of life.

6. ECONOMIC, INDUSTRIAL, AGRICULTURAL, AND FINANCIAL FACTORS. The economic situation of Mexico offers a picture which reflects her level of natural and human resources and her system of economic institutions, both public and private. Mexico is a product of her geography, her demographic structure and movements, and her history, pre-Hispanic, colonial, and independent. Remodeled by her revolution, fought from 1913 to 1925, she is engaged in an economic development which asserts her national independence and adds greatly to her wealth and income measured above all in the general welfare of her citizens—displaying, moreover, an authentic determination to strive with the rest of the world for pacific ends.

Territory.—Frank Tannenbaum has said that "Mexico is a beautiful place in which to live, but a tough place in which to make a living" (*Mexico; the Struggle for Peace and Bread*, Knopf, New York 1950).

Mexico's geography is violent and diversified. In a space equivalent to a little more than one fifth that of the United States including Alaska, her physical geography imposes severe obstacles to the settlement and the efforts of her inhabitants, and to the easy circulation and consumption of the fruits of their labor. Since most of her territory contains rugged mountains, vast deserts, and jungle lands, which can be only sparsely inhabited, there are only limited areas where the temperature and climate, the precipitation and the soil's fertility constitute an environment that is favorable to the full development of an economic culture. Mexico lacks the advantages of great navigable rivers, wide and safe ports, as well as facilities for the laying of the paths of ground communication by means of which her natural resources might attain a maximum value.

But when everything is considered this same varied geography opens up an infinite number of possibilities to the persevering efforts of the Mexicans. On the diverse climatic levels, from the *tierra caliente* (hot land) of the coastal lowlands or subtropical zones to the alpine passes, grow the most varied botanical and zoological species of economic value to man. The geological structure encloses mineral deposits which attracted the greed of conquerors eager for gold and silver, offered modest reserves of iron and coal in the preliminary stages of Mexico's modern industrialization since the beginning of this century, and later added petroleum and industrial and strategic minerals whose exploitation has meant a vital contribution to the economy. Adding to all this a respectable hydroelectric potential, Mexico has sufficient effective assets for waging the battle for economic progress, without the limitations of countries like Cuba, Venezuela, Bolivia, or El Salvador, whose economy is based on one or a limited number of products, or of those other countries to which nature has denied the bases of adaptation to the changing requirements of a modern economy. Her geographic location is to be envied: the wide northern frontier places Mexico right next to the strongest and most prosperous economic power in the world; her coasts look out upon the two great oceans of present-day civilization; and the Isthmus of Tehuantepec links Mexico to a Latin America which considers her the leading partner in the community of Spanish-speaking peoples.

Despite impressive advances since about 1925, the beginning of peaceful and constructive revolution, Mexico has realized barely a minimum part of her economic potential. Perhaps some of her resources have been overestimated through a misunderstood patriotism; also, over broad regions of her territory there exist forms of primitive human life which act as a factor retarding progress, the elimination of which will be slow and difficult. But the deficient knowledge and superficial exploitation of her resources may soon be replaced by a serious inventory and a deep exploration of the Mexican potential, providing gratifying surprises to coming generations, and assuring their full employment to meet the increasing demands of progress. It is generally believed, not solely among Mexicans but especially among foreigners, that Mexico is paving the way to a better utilization of her resources, and that there remain many plus-values to be gained. To climb step by step to more and more elevated levels of this mastery is the ultimate goal and the surest pledge for the future well-being of the Mexicans.

Population.—The total population growth of Mexico is quite considerable, and the rate keeps increasing—in contrast to the highly developed countries of the world. The censuses of population reflect this impressive development: 1930, 16.6 million inhabitants; 1940, 19.7 million; 1950, 25.8 million. During the 1930's the average yearly increase was about 310,000 inhabitants; during the 1940's about 610,000.

This very substantial increase in population possesses a significant economic importance: year after year the demographic increase spells greater pressure upon available resources. But this situation is further aggravated, first, because the economically active population does not grow at the same rate as the total (active population in relation to the total: 31 per cent in 1930; 30 per cent in 1940; 29.5 per cent in 1950); and second, because the agricultural pop-

ulation not only keeps increasing in absolute terms (3.6 million in 1930; 3.8 million in 1940; 5 million in 1950), but also maintained virtually the same percentage level during the decade 1940–1950 in the economically active population of the country (70.6 per cent in 1930; 65.4 per cent in 1940; 58.0 per cent in 1950—this last percentage being similar to that of the agricultural labor force in the United States in 1850).

Transportation.—For the normal economic development of a growing nation, a well-planned, efficient system of transportation is almost unanimously considered as indispensable. The reader is referred to the section in this series on *Transportation and Communications* for this information.

NATURAL RESOURCES

Minerals.—*Precious Metals.*—The proverbial wealth of Mexico in minerals for more than three and a half centuries was based on the circumstance that the precious metals were, according to the ideas of mercantilism, the most conspicuous indication of the wealth of nations and the economic potentiality of states; and that Mexico stood out as the leading producer of argentiferous metal. The entire world accumulation of silver barely totaled 50 million kilograms (a kilogram equals 32.2 ounces troy) until the exploitation of the Mexican mines in the Guanajuato region began in 1555. Since then some 210 million kilograms of silver have been extracted from the Mexican subsoil, the peak of production taking place in the five-year period 1926–1930, with more than 3 million kilograms per year. Despite declining figures (2.6 million kilograms in 1942; 1.36 million in 1951) Mexico still leads in world production, with 42 per cent in 1951, followed at a considerable distance by the United States, a country which exercises the decisive influence over this precious metal by virtue of being the primary purchaser of the product and the principal investor in Mexican silver mining. The decline in silver is not due so much to the exhaustion or scarcity of reserves as to the impact of phenomena manifested since the period following World War I, among them the discard or decline of metallic monetary standards, the oscillations of United States silver policies, and the disturbing effects of political changes after 1946 in countries of the Orient and southern Asia, such as China and India, which in the past fed the demand for silver by their high propensity for hoarding.

In comparison with this extremely valuable Mexican silver production, the exploitation of gold-bearing lode deposits results in quantitatively modest returns. While the productive capacity at the end of the 18th century was, on a yearly average, 1,610 kilograms, with an approximate value of one million pesos of that era, and although the production for 1950 (12,700 kilograms) represented an enormous increase which brought 123.7 million pesos, the income from Mexican gold production occupied only fifth place (see Table 1) in the country's mineral production of 1950, while the income from silver (in third place) in the same year amounted to 312.5 million pesos.

Other Minerals.—In the course of the years other minerals required for the industrial uses of our manufacturing epoch have replaced the

precious metals in their importance to Mexico. At the head of these other products of the Mexican subsoil are zinc, lead, and copper; but the contributions of antimony, cadmium, and manganese are also noteworthy (see Table 1). If to these minerals are added the values of iron (see following section), graphite, tin, mercury, arsenic, tungsten, and bismuth, the value of mineral production in 1949 reaches a total of 1,748 million pesos; in 1950, 2,003 million pesos. The data relative to 1951 soar to figures still higher, in Mexican currency, although strong disconcerting factors are introduced by monetary devaluations and by inflated quotations in the international market, as a consequence of postwar demands directed above all toward building up strong stocks in the United States and using conservatively the reserves of these nonreplaceable products in that country.

Table 1—MINERAL PRODUCTION

	1940		1949		1950	
	Production (tons).	Value (million pesos)	Production (tons)	Value (million pesos)	Production (tons)	Value (million pesos)
Lead	196,000	123	221,000	606	238,000	579
Zinc	115,000	91	178,000	402	224,000	593
Copper	37,600	52	57,000	195	62,000	244
Antimony	12,000	21	5,750	37	5,878	31
Cadmium	816	8	820	31	130	2.5
Manganese	307	a	24,000	15	14,461	10.2

a Not available.

Coal and Iron.—Three nonreplaceable raw materials of the Mexican subsoil present problems of a different character: coal, iron, and petroleum. Coal and iron are the mainstays of industrialization. Unfortunately, these reserves are not the ones that define Mexico's mineral wealth. The total production of pit coal, extracted almost entirely in Chihuahua, barely exceeds a yearly average of one million tons (0.05 per cent of world production). A lack of progress in the exploitation of known deposits is revealed by the fact that the average monthly extraction in 1937 was 103,500 tons, a figure not attained in any month in 1950. Known reserves are estimated at about 2,000 million tons (the world production for one year). It is only comparatively recently that the Oficina de Investigaciones Industriales of the Banco de México has attacked the problem of redeeming for the iron and steel industry the losses of raw material (about half) due to inadequate techniques in the coking process.

The full use of modern treatment processes, and the possibility of extending and deepening the geologic-mineral explorations and of incorporating the new districts of Coahuila, Oaxaca, and Chiapas in the Mexican reserves, may alleviate the extreme scarcity of the present situation.

Nor is the panorama of iron deposits much more attractive. A deposit of good quality (60 per cent) in the Cerro de Mercado of Durango has been the basis for the siderurgical prosperity of Monterrey for half a century, but despite the first fantastic expectations, the estimated reserves do not exceed 50 million tons. Including a great number of small lodes scattered mainly among the states in the north of the republic, there exist barely 200 million tons (a trifle more than 0.5 per cent of the world reserves).

The gravity of the problem is immediately patent in the following figures: the quantity of mineral extracted in 1940 was just over 70,000 tons (175,000 in 1945; 285,000 in 1950). In 1940 iron and steel production was 130,000 tons, and it registered a constant increase until 1947 (300,000 tons), but imports of iron, scrap, and steel were also considerable (88,000 tons in 1940; 312,000 in 1947), giving together an apparent consumption of 218,000 tons in 1940, of 612,000 in 1947, and of 668,000 tons in 1950. At this primordial line, the subservient position of Mexico's iron and steel production is evident, in times when the threatening possibility exists that such extremely necessary imports may fluctuate in relation to international events. This problem and that of locations made compulsory by the presence of the deposits, with the ensuing transportation complications, mean great obstacles to the industrial progress and satisfaction of the consumption needs of the country.

Not everything spells limitation, however: Jenaro González Reyna, Luis Torón, Adrián Esteve, and Leonardo Martín Echeverría, with excellent knowledge of the possibilities of Mexico, state that until now the geologic-mineral investigations in Mexico have been deficient and superficial. Carried to greater depths in the earth by means of a laborious effort of many years, they may discover—and this the geology of Mexico leads one to suppose—new and extremely important deposits, and what is still more important, locations that are more strategic and in better combination, to answer the increasing demands of Mexican industrialization and consumption.

Mining Policies.—The main problem of Mexican mining is the clash of interests between foreign investors and the Mexican economy. Foreign investments in Mexican mining were 626 million pesos in 1940 and 892 million in 1948. Including the nationalized production of petroleum and natural gas, this economic sector gave employment to only 1.82 per cent of the economically active population, the same in 1940 as in 1950. Thus we have the paradox that the mining labor force presents the highest index of productivity among all activities, but this quite deceptive appearance fades when we recall the relatively high capitalization in mining.

A concrete fact is the high fiscal income issuing from the mining enterprises. In 1951 they paid 800 million pesos in taxes to the government, an amount comprising 20 per cent of the federal income; the value of production of mining enterprises being only 5.84 per cent of the gross national product in that year. The mining entrepreneurs complain that the government has abandoned them, as evidenced by such a heavy tax burden and by the fact that the greater part of government incentives is concentrated in the field of manufacturing enterprises. In the opinion of the miners, the extractive industry languishes for want of a strong stimulus—without reaching the high productive figures of 1926–1929—and thus the bases for the success of the industrial programs are reduced and narrowed.

The government, however, justifies these high tax charges by the fact that minerals constitute an exhaustible reserve whose earnings for the most part go to foreigners, aggravating the problem of deficits in the balance of payments—an injury even more revealing when one considers that it is necessary to import the finished products of Mexican mineral raw materials in order to satisfy the needs of ultimate consumption and, above all, of equipment for manufacturing plants in Mexico.

Without a doubt, Mexican mining enterprises

have not passed beyond the most elemental levels in the field of transformation industry (preparation of concentrates), due to which circumstance mining products account for a high percentage of the load carried by Mexican railroads, a factor deeply disconcerting to the country's very poor system of transportation.

The only viable solution in this field would consist in leveling the taxes imposed on mining until they were fixed at a rate similar to other incomes derived from capital. In exchange for this, the enterprises should undertake to compromise so as to reinvest a sizable portion of their profits in installations of high transformation, capable of producing a part of the articles needed for national consumption, thus saving production costs, tariffs, and costs of insurance and transportation, all of which are at present ultimately shifted onto the Mexican consumer.

Petroleum.—In dealing with the Mexican petroleum problem, the temper of the nation and the will of its leaders are fully revealed. The *chapopote* of the natives before the conquest, the *stercor diabolus* (devil's dung) of the missionary friars, petroleum has been the best exponent of Mexican history in the 20th century. In 1900 and 1901 Englishmen and United States citizens began drillings in the Isthmus of Tehuantepec and in La Huasteca (Lower Pánuco River region), respectively. In the rich zone called Faja de Oro, in Veracruz, a concession of the British company El Águila, the well Potrero del Llano No. 4 gushed forth in 1910, and its production in a few years reached the incredible figure of 157.1 million barrels (1920), to which were added healthy contributions from the fields of the Huasteca Petroleum Company and the Poza Rica zone in Coatzintla, Veracruz.

At the beginning of the 1920's (maximum production, 1921: 193.4 million barrels) Mexico was second in world production, although considerably below the United States. But the appearance of strong, successful competitors in the world market, particularly Venezuela, brought Mexican production to a low of 32.8 million barrels in 1932, in the midst of a world depression. As a defense against unilateral decisions of the petroleum companies, in an attempt to guard this valuable asset of national patrimony by removing it as much as possible from the fluctuations of the world market, and in order to satisfy the requirements of Mexican transportation and of industry, President Lázaro Cárdenas decreed the nationalization of petroleum on March 18, 1939, relying upon the legal basis of the Mining Ordinances (Ordenanzas de Minería) promulgated by Philip II in 1559 and Article 27 of the Constitution of 1917, and upon the assent of all sectors of opinion of the Mexican people. The Mexican professor Jesús Silva Herzog and the Committee on Interstate and Foreign Commerce of the United States House of Representatives have each described with considerable erudition (see *Bibliography*), and each from a different point of view, this transcendental event, viewed by foreign investors and governments as one of the worst attempts against the institution of property and human rights. Since that time the ability of the Mexican people to attempt a technological exploit reserved until then for the oligopolies of the great industrial powers has stood trial. (See also the following subsection on economic policy.)

The report of the director of Petróleos Mexicanos (which exploits the nationalized petroleum resources), published March 18, 1952, summed up the strides made in these terms (comparing the years 1946 and 1951 except as noted): the crude petroleum reserves increased from 1,058 million barrels to 1,424 million; adding the equivalents of reserves of natural gas and distilled products, the hydrocarbon reserves of the nation rose to 1,796 million barrels. Annual production increased from 49 million barrels to 79 million. The number of wells drilled in 1951 was 268, as compared with 64 (1947). Refining plants at Azcapotzalco, Federal District; Salamanca, Guanajuato; Reynosa, Árbol Grande, and Ciudad Madero, Tamaulipas; and Mata Redonda, Minatitlán, and Bella Vista, Veracruz, went from a production of 42 million barrels (1945) to 57 million (1951); distributed products rose from 34 million barrels to 50.6 million. Exports were raised from 9.7 million barrels to 22 million. Revenues of Petróleos Mexicanos rose from 570 million pesos to 1,839 million ($66 million and $213 million, respectively). The sum invested in explorations rose from 28 million pesos ($3.3 million) to 177 million pesos ($20.4 million). Taxes paid to the Mexican government increased from 191 million pesos ($22 million) to 505 million ($58 million); that is to say that the nationalized petroleum industry by itself yields five sevenths of the taxes derived from the country's mining activities.

All these facts, together with the advantage afforded by natural gas, the production of sulphur and fertilizers, the presence of an attractive formula for subsoil exploitation by nationals and foreigners, and the low selling price of the product in the internal market constitute an extremely favorable outcome to the daring patriotism of the Mexicans, and permit the hope that the industry will continue to meet the requirements of an increasing consumption and also produce an exportable surplus to invigorate the balance of payments.

Electric Energy

Perhaps one of the most eloquent indices of the economic development of Mexico is that expressed in the increase registered by the generation and consumption of electricity, for residential purposes as well as for those associated with the production of goods and services, in the private sector and in the public. In 1933 the total generation of electricity was 1,529 million kilowatt-hours, of which 204 million were generated privately by industry and 23 million were imported, with a total consumption of 1,351 million kilowatt-hours. The corresponding figures for 1950 were a total of 4,423 million kilowatt-hours generated (1949.5 million hydroelectric; 2474.0 million thermic), 874 million generated privately, 125 million imported, and a total consumption of 4,187 million kilowatt-hours. The total billing recorded by the Dirección General de Electricidad was for 208 million pesos in 1949, and 383 million in 1950. Despite this and a tripling of the supply of electricity since 1930, the demand, stemming mainly from industrialization, above all in the Federal District, and the Puebla-Veracruz, Chihuahua-Nuevo León, and Jalisco regions, is still greater.

In those areas provided with electricity, the consumption per capita is very close to that of the United States taken as a whole. But this picture changes entirely when one considers that in 1950 only 13 per cent of the Mexican population enjoyed the benefits derived from electricity.

In addition to the companies that initiated the country's electrification in the early years of the present century, led by the powerful Compañía

Mexicana de Luz y Fuerza Motriz, the government also has been seriously concerned with the problem of creating, through juridical regulations and direct promotions, the bases for this service, so fundamental and indispensable to the fostering and growth of Mexican industries and services. The Comisión Federal de Electricidad (Federal Electricity Commission) was instituted on Aug. 14, 1937, and is governed by the statute of Jan. 14, 1949. Its objective is to "organize and direct a national system of generation, transmission, and distribution of electric energy, on a nonprofit basis, with the aim of getting the greatest possible returns at a minimum cost for the benefit of the general interest." Its most important creation is what is now called the Sistema Hidroeléctrico Miguel Alemán, which was actually begun in 1937 during the administration of Lázaro Cárdenas, and is scheduled for completion in 1957. This comprises seven hydroelectric plants with a total capacity of about 404,000 kilowatts.

The most pressing problems of the immediate future consist in raising the capacity of generation to such an extent that lack of electricity will not curb the country's economic development, and then achieving the standardization of frequencies and voltages. During the years 1948–1950 more than 670 million pesos were invested by the Comisión Federal de Electricidad, the Compañía Mexicana de Luz y Fuerza Motriz, and the Nueva Compañía Eléctrica de Chapala. The major portion of investments were made by the Comisión Federal, which utilized more than 300 million pesos in international credits; the Compañía Mexicana obtained a credit of $25 million in 1949 from the International Bank of Reconstruction and Development, guaranteed by the Mexican government; the Eléctrica de Chapala in turn received a credit of $3.5 million which it invested almost entirely between 1948 and 1950. Forty-two per cent of the investments were made through internal financing and the remainder originated in international organizations.

Fishing

Of the five large fishing areas into which the country is divided, and which produced a total of 125,000 metric tons in 1949, the most important were Zone 1, comprising North and South Lower California, Sonora, Sinaloa, and Nayarit (1949 production, 100,000 tons; valued at 40 million pesos), and Zone 2, comprising Tamaulipas and Veracruz (1949 production, 13,000 tons; valued at 19 million pesos). The two main species caught were tuna fish (50,000 tons, in 1948; value 116 million pesos) and shrimp (18,000 tons in 1949; value 42 million pesos).

Those employed totally or partially in this extractive industry number some 20,000 persons, although the number of fishermen organized in cooperatives does not exceed 9,000. The local character of much of the fishing—mainly in marshy waters along the coast—the inadequate operating equipment (most of the boats are less than three-ton), and the limitation of the internal market (consumption in large internal urban centers continues to decrease), are decisive factors in the low production and reduced income obtained by the fishing community.

On Oct. 25, 1945, Mexico reaffirmed her sovereignty over her continental shelf, presupposing an extension of her jurisdiction much farther than the nine-mile limit to jurisdictional waters in effect since 1935. A recognition of this declaration, especially by the United States and Cuba, would avoid numerous conflicts brought on by discussions over limits and invasion of these areas by the fishing operations of foreigners.

AGRICULTURE

Land Reform.—Since the birth of the movement for independence in 1810 the greater mass of Mexicans have felt, in a silent, vague manner, the desire for access to possession of land. Neither the disentailment (*desamortización*) law nor the Reform Laws, of the 19th century, succeeded in fully destroying the colonial structure of land tenancy, and the reforms of Porfirio Díaz strengthened the hacienda system based on large estates and the servile condition of rural laborers, instead of establishing the foundation for a thorough agrarian reform. In 1910 it was estimated that two per cent of the population owned over 80 per cent of the land, and that 80 to 90 per cent of the rural population was landless.

The revolution of Francisco Madero (1910–1911) confined itself to overthrowing the juridical and political apparatus of the Porfirian regime. It was the armed uprising (1911) of Emiliano Zapata in Morelos, and his demand that the lands be restored to the people, that communicated to the entire country the galvanic emotion of a profound agrarian revolution. The first official reaction was the promulgation of the law of Jan. 6, 1915, issued by Venustiano Carranza in Veracruz, whose principles were embodied in Article 27 of the Constitution of 1917. This article recognized the social function of private property; the right of towns, villages, and communities to be endowed with land and water; the setting of a maximum to the properties of each economic entity, whether individual or collective; the special protection of small property; and the eminent dominion of the nation over the soil and subsoil.

There was great faith in the thaumaturgical powers of the legal text, in the idea that a mere change in ownership or dominion would solve the problem and satisfy those who were so eager for land. But distributions without adequate title, brought about in an anarchical manner, could not serve as a firm base for the reform; nor could the peons on former estates or in villages change

overnight into people with the mentality of nonwage-earners, into technicians capable of valuing the lands assigned to them to their own advantage and that of the country; nor did their education permit them to submit to the rigors of a collectivist discipline, and neither they nor the country possessed the credits and equipment necessary for carrying the technological revolution into the fields. A brilliant Ley de Crédito Agrícola (Agricultural Credit Law) composed by learned jurists, which clearly stated problems and solutions, did not go beyond being an item in the files; nor did the Banco Nacional de Crédito Agrícola y Ganadero (National Agricultural and Livestock Credit Bank), established March 8, 1926, have better luck, except in some few districts where there happened to be self-denying, energetic men as directors.

President Cárdenas gave the widespread spirit of the agrarian reform a legal vigor and condition of fact by the Código Agrario (Agrarian Code) of 1934, extensive distributions of land, and the institution of the Banco Nacional de Crédito Ejidal in 1934, which gave each large rural sector its own credit organization. His period in power (1934–1940) represents the peak in the distribution of large estates.

LAND DISTRIBUTION

	Hectares (= 2.471 acres)	Persons Benefited
1915–1921	453,000	86,000
1922–1933	7,000,000	700,000
1934–1940	18,000,000	1,250,000
1940–1946	6,000,000	165,000
1946–1950	1,800,000	43,000
Total	33,253,000	2,244,000

During the 35 years ending with 1950, 33.3 million hectares were granted, by means of some 20,000 definitive titles, benefiting in all about 2,240,000 countrymen. The *ejidatarios*—individuals participating in *ejidos* (communal village lands)—numbering 2.3 million in 1951, possessed a total of some 32.3 million hectares; of which 1.5 million were irrigated lands, 7.97 million were seasonal, and 22 million were not tillable. The average area under cultivation per *ejidatario* was 4.63 hectares —actually narrowed to an average of 2.72 hectares because seasonal lands are only cultivated at a yearly rate of 50 per cent in order to replace their fertility. The average of pasture and woodlands was 12.93 hectares.

The insufficiency of available land for the rural individual is disclosed in the following data from the 1940 census: of the 1,233,609 registered pieces of land property, some 40 per cent consisted of less than one hectare and another 35 per cent involved parcels of between one and five hectares in size, a proof that the agrarian reform was determined to give lands to all who sought them, rather than to fix an adequate minimum for the parcels distributed. According to provisional figures from the 1950 census, of the 1,370,625 registered pieces of property, 993,545 were of less than five hectares.

The distributions become more and more difficult because in order to assign lands it becomes necessary to resort to lands divided previously, to reduce still further the *ejidal* parcels, or to effect difficult transfers en masse; all this without including the fact that the powerful increase in population imposes an ever greater human burden upon a rigid availability of lands. Traditional agrarian thinkers, with an advanced ideology, would like to carry the distribution to its definitive level, adhering to the legal codes and limiting or curbing a new growth of large estates through political influence. Other groups would like to turn the agrarian reform into a purely technological revolution in order to consolidate in behalf of the farmer conquests which now stand in danger because of a lack of efficiency and productivity on the part of the beneficiaries. There are also those who recommend proceeding with extreme caution in the future, since a radical change either way may sink a group comprising the most important portion of the economically active population of Mexico in utter misery.

According to the 1950 census, of the total of 18.2 million hectares under cultivation in Mexico, 14.7 million were unirrigated, seasonal arable lands, with sparse, uncertain rains, about half of which are cultivable each year; those with irrigation amounted to 2.3 million hectares, and 1.2 million were moist or humid lands (*tierras de humedad*), needing additional irrigation in some cases. It is in the first group above all that the harmful effects of erosion, the wild character of the terrain, deficient communications, damages caused by irrational cultivation, scarce investments, and similar circumstances are to be found, made even worse by the high growth of population in the zones of this group.

Irrigation.—The Comisión Nacional de Irrigación, founded in 1926, added 271,000 hectares to the available irrigated lands between 1929 and 1940; since the latter date and 1950, 1.2 million hectares have been benefited by irrigation works, to which 54,700 hectares were added in 1951 and 325,400 (provisional figure) in 1952. During the first three years (1947–1949) of the six-year plan ending in 1952—a period of vigorous action by the Secretaría de Recursos Hidráulicos (Department of Hydraulic Resources), a federal government department created on Dec. 21, 1945 as successor to the Comisión de Irrigación—the area benefited was 307,000 hectares (in addition to the area mentioned above), a bit more than one fourth of the total of 1,147,000 hectares which were to have been added, at a cost of more than two billion pesos.

Crops.—The very wide zone of traditional agriculture offers few possibilities for technological reform. The predominant crop is corn, mostly consumed by the families of the cultivators themselves, with little remaining for the market. In this type of cultivation there is no crop rotation, merely an insertion of beans to complete the wretched rural diet. On the other hand, the lands under "new agriculture" open up a field that is propitious for the cultivation of plants like cotton, sugar beets, or oilseeds, whose product is destined almost exclusively for the market, at the most profitable revenue levels. Such crops serve as raw materials for industry, or are intended for export.

Corn.—This grain, grown almost everywhere in Mexico, constitutes one of the gravest problems of the country's agricultural economy.

CORN PRODUCTION

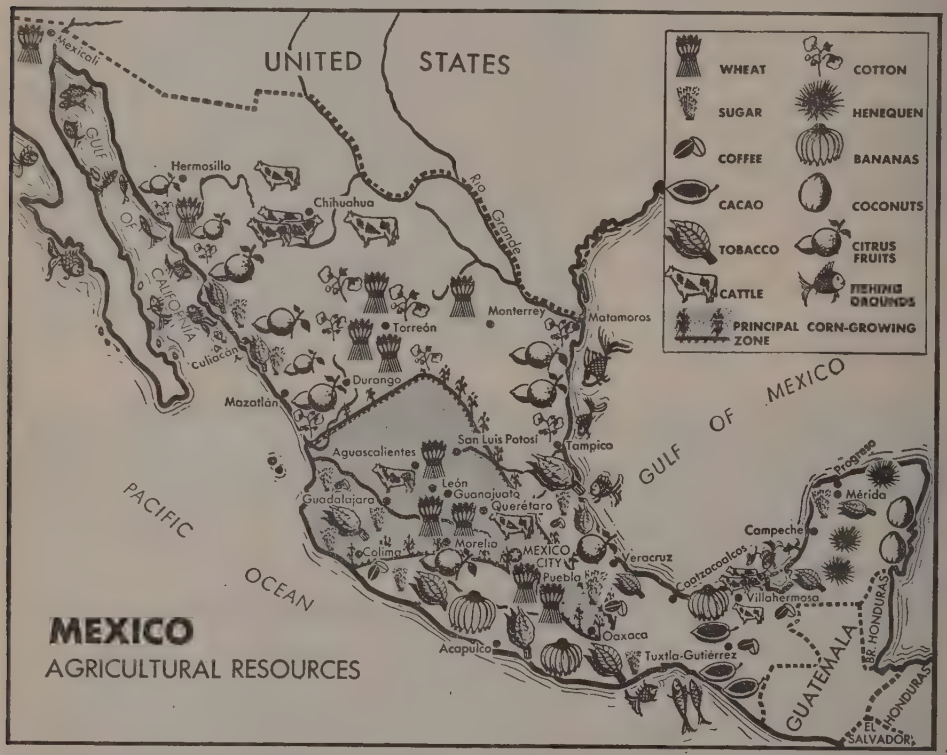
Year	Area harvested (hectares)	Production (metric tons)	Yield per hectare (kilograms)	Value (million pesos)
1950	4,327,722	3,122,042	721	1209
1951	4,427,696	3,424,122	773	1711
1952	4,712,078	3,699,343	780	1984

Major advances were achieved thanks to genetic studies made in experimental agricultural camps under the Instituto de Investigaciones Agrícolas and the Oficina de Estudios Especiales (Rockefeller Foundation) of the Secretaría de Agricultura y Ganadería (Department of Agriculture and Livestock). Despite these efforts, however, this grain has frequently been imported, in some years in volumes as considerable as 109,000 tons (1926), 117,500 (1933), or 162,800 (1944).

According to investigations by the engineer Ernesto Reza Rivera, the average annual corn production in the five-year period 1930–1934 was 1.8 million metric tons and the average rural price per ton was 56 pesos; while in 1945–1949 the average annual production was 2.6 million tons and the price was 385.50 pesos per ton. This tremendous price increase is expressive of an inflationary tendency, made acute by devaluations and other causes, phenomena which are also reflected in the production values, which increased almost tenfold from 1930–1934 to 1945–1949.

Wheat.—Special attention is merited by the case of wheat, whose consumption almost doubled in the 20 years from 1930 to 1949, in answer to pressure exerted by the demand of sections of the population which are entering more generous diet zones. Comparing the five-year periods 1930–1934 and 1945–1949: the average annual production registered only a slight advance (391,000 metric tons to 418,000 metric tons); the average rural price per ton rose (103.60 pesos to 417.20 pesos), though not to the same degree as the price of corn.

The sizable deficit registered by this cereal in relation to consumption needs, and the displacement of the interests of farmers toward other more profitable cultivations (like cotton and oilseeds) are shown in the heavy wheat imports that were required: 122,000 tons in 1940; 447,000 tons in 1948. An interesting fact to be underscored is that in the 1944 the importation figure (509,000 tons) was greater than the production figure (374,000 tons).



WHEAT PRODUCTION

Year	Area harvested (thousand hectares)	Production (thousand metric tons)	Yield per hectare (kilograms)	Value (million pesos)
1950	644	587	911	322
1951	672	589	873	443
1952	666	594	892	466

Cotton.—The cultivation of cotton has shown a vigorous increase, especially since 1946, due to full use of the soils of the Laguna district in Coahuila, and also areas of Chihuahua, Northern Lower California, Durango, and Tamaulipas. The cultivations are achieved entirely under a system of irrigation. Although the returns are far from those of the traditional cultivators of cotton in other countries, the yields have not only permitted Mexico to become almost entirely independent in regard to raw materials for domestic industry, but also provide a sizable surplus which, along with the higher prices in the world market and other favorable circumstances, furnished a great incentive for the expansion of the cotton plantations.

A motive for concern, however, is the fact that relief of international tension, together with agronomical advances in other productive areas of the world and a partial stagnation in the Mexican textile industry, can create serious fluctuations in foreign demand and disturb the development of the Mexican cotton economy. The United States absorbed nine tenths of the cotton exports in 1950, at a value of 761 million pesos.

COTTON PRODUCTION

Year	Area harvested (hectares)	Production (metric tons)	Yield per hectare (kilograms)	Rural price per ton (pesos)
1950	760,500	260,019	342	6,019
1951	883,504	287,612	324	5,226
1952 [1]	775,225	258,640	332	4,794

[1] 1952: provisional figures.

Henequen.—Within the Mexican agricultural economy, henequen—a hard fiber resembling sisal, but coming from the *Agave fourcroydes*—represents a monoculture in a region especially endowed with very suitable soil conditions, the Yucatán Peninsula. Until 1915 Mexican henequen production regulated the world export market for this fiber. Competition from new productive areas, the Philippines and Indonesia, the social repercussions of the revolution and the agrarian reform, as also the relative technological stagnation of the Mexican henequen centers—which, at first, gave their traditional technique and even their mechanical inventions to those countries interested in this crop—resulted in a decline in production, still further increased by the substitution of other products similar to henequen. Between 1930–1934 and 1945–1949 the average annual yield declined from 1,146 to 798 kilograms per hectare; production remained stationary, at a little more than 100,000 metric tons annually between 1930 and 1952. As far as the total value is concerned, there has barely been a nominal increase, corresponding to the loss in purchasing power of Mexican currency.

Coffee, Vanilla, Chick-peas.—Other export crops, such as coffee, vanilla, and chick-peas, have experienced serious reversals since 1948, without asserting themselves as products of fundamental permanence in the agricultural economy of Mexico.

Coffee, produced mainly in Veracruz, Chiapas, and Oaxaca (70,837 metric tons in 1952), maintained the same values, almost without modification, between 1930 and 1949, but the yield declined. One of the causes of the decline, it is believed, was the expropriation of German-owned coffee plantations during World War II.

Vanilla encounters difficulties in competition from synthetic products, and although production has been increasing since 1935 (179 tons in 1952), at values that likewise have increased (9.2 million pesos in 1950), it does not show signs of establishing itself securely as a promising crop for the future. Vanilla is produced chiefly in Veracruz.

The chick-pea (*garbanzo*) harvests, mainly from Sinaloa, Guanajuato, Jalisco, and Michoacán, traditionally went to Spain, almost the sole purchaser. The decline of this market resulted in an accumulation of stock from several harvests, with the exchange operation (1951) with Spain relieving the situation only in a passing manner. Production in 1952 was some 83,000 metric tons.

Livestock.—The extensive grazing and cattle-raising regions in the north of the country, despite the absence of a steady supply of water, managed to acquire the importance predicted by the early leaders of the struggle for independence. However, the internal market, because of poor communications with the large consumer centers in central Mexico, failed to provide sufficient stimulus. Thus, cattle-raising (14.4 million head in 1948; value, 2,872 million pesos) was oriented primarily toward exportation "on the hoof" to the United States, but the *aftosa* fever epidemic (hoof and mouth disease), which affected many states of the republic after 1947, meant the total suspension of such commerce until 1951. In this situation only the meat-packing industry managed to benefit when heavy demands from European countries in the first years after World War II resulted in an atmosphere of prosperity for such enterprises. Production in 1950 was 14.8 million head.

INDUSTRY

Process of Industrialization. Mexico's desire to become industrialized dates back to the beginning of its independent life (1821). Certain patriotic and learned statesmen, such as Lucas Alamán (1792–1853), were concerned with offering government help—in a modest but well-meant gesture of federal aid—so that the country might benefit immediately from the technical advances of the Industrial Revolution which started in England and certain regions of the Old World. In the field of the entrepreneur, Esteban de Antuñano founded La Constancia Mexicana in Puebla in 1837. This was the first modern textile company in Mexico, as measured by the standards of the time. In the public field the Banco de Avío and the Dirección Industrial were established in 1831; the former to finance the importation of machinery and raw materials for private concerns, the latter to implement the new economic policy. Their great interest lies in the fact that they reflect a youthful but decided sense of planning, inspired by the necessity of furthering, in accordance with Mexican aspirations, an industrial development whose integration was hindered by demographic, politico-economic, fiscal, and educational problems.

These farsighted men, acting in difficult times and with poor resources, believed that industrialization must not grow as an isolated vine, but must surround itself with other developments; it must not mean the wealth of a few fortunate entrepreneurs but must bring about a general welfare. This inspiration was renewed a century later, after the Revolution of 1910. On its correct application, without forgetting any useful factor, depends the successful future of Mexico.

The Liberal epoch, strongly evident in the Constitution of 1857, although fortunate in many other aspects, was not as successful in its attempt to accomplish the industrial development of Mexico as was the previous period. The greatest accomplishment was in the epoch—politically a dictatorship—in which Gen. Porfirio Díaz ruled (1876–1911). The present industrial development of Mexico dates from the last 20 years of the 19th century. It is reminiscent, particularly in the emphasis on transportation, of the growth of Germany in the time of Georg Friedrich List (1789–1846), although on a smaller scale.

This earlier concern for industrialization was interrupted by the widespread revolutionary activity between 1910 and 1925. During this period, the peaceful atmosphere and the right institutional organization for a definite progress in the production field were lacking.

The brilliant and well-aimed administration of Gen. Plutarco Elías Calles (1924–1928) provided the bases of organization for subsequent steps up to the present. The administration of Gen. Lázaro Cárdenas (1934–1940) emphasized agrarian reform, attempted to incorporate the great Indian masses into the cultural work of the country, converted the labor class into the forgers of Mexico's future, and strongly affirmed Mexican economic sovereignty in regard to the nationalization problem, as evidenced in the petroleum industry and railroads. His aim in industrialization was directed toward processing the soil's products to the greatest possible extent in their place of origin, in order to avoid the disadvantages emerging from a concentration of manufacturing in urban centers.

With less emphasis on the agrarian revolution, although still endeavoring to create a farmer with sufficient purchasing power, Gen. Manuel Ávila Camacho's regime (1940–1946) underscored the necessity of industrialization for the economic progress of Mexico—in addition to his cooperation in the war effort of the democratic powers in World War II. The early 1940's were a period of weak investments by industrialists, both nationals and foreigners. Some economists attributed this partial withdrawal to fear that new and important industrial promotions would be in danger of a future nationalization program by the government. In the opinion of others, however, much capital available for investment had been liberated as a result of the agrarian reform, and awaited only the advent of the proper occasion for new industrial undertakings. That opportunity came during the administration of President Ávila Camacho. The outbreak and spread of World War II deprived Mexico of imported necessities and encouraged investors to establish light industries, to expand those that could provide basic products, and to improve necessary public services. The government, by offering investors valuable incentives, also contributed to this development. Among the encouragements offered, the Ley de Industrias de Transformación (Transformation Industries Law) of April 21, 1941 (amended Dec. 31, 1945) may be mentioned as an example. This provided for important tax exemptions for new and necessary industries with respect to machinery, equipment, and importation of raw materials, and it also eliminated the fiscal encumbrance of the first schedule of the income tax for maximum periods of from 5 to 10 years.

The Oficina de Investigaciones Industriales of the Banco de México, which supervised the implementation of the above-mentioned law, obtained complete information on nearly 900 industries benefited by this plan, and provided the government with very useful criteria for a future program of industrial protection. Of course some of the industries that arose as a result of the incentives offered by the law disappeared when World War II ended and foreign competition re-entered Mexico and the international market. The majority, however, subsisted and even improved; this being, together with the presence of older companies and those that were modernized, the reason for the obvious industrial progress of Mexico during the presidential term of Miguel Alemán (1946–1952).

Evidence of the progress achieved is found in the fact that government pump-priming is no longer necessary to industrial investment. An effort is being made, thanks to acquired experience, to channel new investments into fields where gaps are still to be found, preferring a localization that will fit national industrialization into an integrated plan. At the same time, an attempt is being made to promote companies producing basic materials used by secondary industries, in order to reduce the economy's dependence on foreign economies, whose cyclical oscillations disturb Mexico's development. This does not mean, however, that Mexico expects to attain an impossible self-sufficiency; the object is to push the available means, now increasing in number, to the purchase of capital goods, so necessary in sustaining the rhythm of industrialization.

Debate Over Basic Policy.—There has been a great controversy, international in scope, in regard to this subject. As far as the Mexicans are concerned, industrialization is justified for many reasons, among them the following: the fact that it concerns a country which has a diversified economy; the necessity of absorbing—especially in the

secondary industries—important numbers of the excessive farm population; and the convenience of giving foreign companies an opportunity to make sizable profits, while at the same time preventing the continuous drain of natural resources resulting from the exportation of exhaustible raw materials. Foreign writers, for their part, have generally tried to show the advantages of an international division of labor, making of Mexico a nation limited essentially to providing the superindustrialized countries with raw materials. Those countries furnishing capital feared that Mexico, with its limited financial resources and with its exportations of raw materials as the almost exclusive source of its wealth, would not be able ultimately to sustain its industrialization rhythm without falling into painful and repeated devaluations. The fact is that despite an almost permanent deficit in its balance of payments, Mexico is reaching higher and higher levels of development and is directing its policies toward the safeguarding and improvement of the positions gained.

The persistent attempts of authors in the United States to analyze the problem is to be highly appreciated—with regard to industrialization, especially the efforts of Sanford Alexander Mosk (see *Bibliography*) and Frank Tannenbaum, who, in *Mexico, the Struggle for Peace and Bread* (1950), adopted the view of industrialization held by the Cárdenas administration (1934–1940), mentioned above. Their recommendations emphasize the necessity of attaining a more considerate and proportionate development of the human and material resources actually available. If in some cases a return to the "philosophy of small things" is suggested, this advice does not mean a return to rural and backward forms, but reflects a desire to rescue the unmistakable human qualities of the Mexican from the destructive forces of urban crowds arising from the rapid progress of industrialization.

The fundamental aim of the industrialization program is the creation of a large national market for industrial products on the basis of a healthy stability, even an increase, in the farmer's income. Thus a fruitful industrialization, pleasing to Mexican patriotism and constantly attempting to raise the people's income, is advancing by firm steps. Mexico has sufficiently demonstrated its capacity to produce more and more of the goods which satisfy its economic needs; the government aims at developing an equal ability to raise the general purchasing power of the masses of its population, so that all its inhabitants may reach a higher and more satisfactory standard of living.

Production.—Industrial production has registered an amazing development: its total value increased from 2,113 million pesos in 1939, to 9,514 million in 1946, and to 16,794 million in 1950, according to data quoted by Ramón Beteta, then secretary of the Treasury. These data to a large extent reflect the effects of monetary devaluation. But taking the total volume of production in manufacturing in 1939 as a base equal to 100, the percentage for 1946 was 174.6 and for 1950, 228.2. If industrial production is considered as a whole, including manufacturing, mining, petroleum, and electric energy, the flow of industrial goods seems to increase at a yearly rate of 4 per cent (between 1939 and 1948, a total increase of 35 per cent).

In the following paragraphs is a summary of data of some of the heavy and light industries most characteristic of the modern industrial development of Mexico. These are only small samples of the industrial development which has reached all manufacturing branches, with the exception of those which, because of the large amount of financing required, because of the lack of an internal market, or because of the need of costly equipment for technological investigation, are not within the reach of the present level of Mexican economic development, but are reserved, so far, for the superindustrialized countries. This is the case with industries manufacturing heavy machinery, highly accurate scientific instruments, and even transportation vehicles. In the latter case, a solution was sought in plants assembling automobiles from imported parts, but this experiment was not completely satisfactory to the country's consumers, who did not find lower prices for the same quality. An enterprise sponsored by Italians, which was promoted in 1951 in an attempt to solve the problem of freight transportation on highways, is assembling diesel trucks, and plans to enter the manufacturing field at a later stage.

Iron and Steel.—The only company producing pig iron at the beginning of the present century was the Compañía Fundidora, of Monterrey, whose first furnace started production in 1903 with a volume of somewhat less than 22,000 metric tons a year. (All tons in the following are metric.) In 1950 it had two furnaces, with a daily theoretical capacity of 800 tons, and the annual production amounted to a total of 119,000 tons of pig iron and 139,000 tons of steel. La Consolidada, founded in 1912 (with branches in Piedras Negras, Coahuila; Mexico City; and Tlalnepantla, State of Mexico), had open-hearth furnaces with a yearly theoretical production of 100,000 tons of ingots in 1950, producing mainly from scrap from northern Mexico and the southern United States. A third large enterprise, Altos Hornos de México, rose in answer to the limitation of supplies caused by World War II. It was financed by the Nacional Financiera, a government institution, and was established at Monclova, Coahuila, in 1942. It was limited initially to the production of steel and tin plate, begun in 1944, and it has a furnace with a daily theoretical capacity of 250 tons.

The volume of production of the iron and steel smelting plants in Mexico was 164,000 tons in 1943 and 300,000 in 1950, with respective values of 73.5 million and 415 million pesos. This, in 1950, represented a little over 9 per cent of the total value of the country's manufacturing production. Scrap importation, almost exclusively from the United States, was 119,000 tons in 1950. The importation of iron (pig iron) and steel (ingots and bars) totaled 30,000 tons, with a value of 22 million pesos, in 1950. For the same year the importation of iron and steel goods was 360,000 tons, with a value of 250 million pesos.

The most important problems of this branch of industry are the scarcity of iron deposits and their wide separation; the same is true of the limited supply of coking coal. Important coal deposits of low content were investigated in the Oaxaca zone in 1950 and thereafter. To those shortages must be added serious deficiencies in the transportation system and the exportation of some quantities of iron ore for processing outside Mexico. In 1950 this reached the considerable mark of 192,000 tons. Geological conditions and coking possibilities by modern methods are being studied by the Oficina de Investigaciones Industriales.

Cement.—This has acquired a central significance among construction materials. As late as 1900, cement had to be imported from the United States and Germany. The first factory was estab-

lished in Mexico in 1903; in 1950 there were 12 plants in operation, with a production of 1,480,000 metric tons valued at 148 million pesos (in 1939, 537,464 tons and a value of 22 million pesos). With a yearly rate of growth of 11 per cent of its volume of production, this industry is one of the most forceful in the country and one of the main supports of its development. Importation is practically nil (3,000 tons in 1950). In spite of local progress, this industry is faced with the problems of balancing the supply with an increasing demand, giving a correct location to new plants, organizing transportation and distribution, and taking advantage of favorable conditions for the exportation of its products.

Rayon.—The first governmental attempts to stimulate the building of a rayon factory appeared in 1935. In 1942, thanks to financing by the Nacional Financiera, La Celanese was established in Ocotlán, Jalisco, starting production in 1947 with 2,000 metric tons. In 1950 it produced 5,000 tons, with a value of 81.5 million pesos. This initial step was followed by the founding of a plant in Zacapu, Michoacán, with a production (1950) of 3,000 tons a year. At the same time, imports, which amounted to 3,240 tons in 1946 (the entire rayon consumption of the country) and to 1,435 tons in 1950, have been reduced. The main problem is the dependence of this industry on its raw material, cellulose, which must be imported. The production of cellulose in Mexico is one of the important goals to be pursued in the coming decades of the economic development of the country.

Fertilizers.—Among the chemical industries, a group which attained the most impressive progress after 1940, those manufacturing fertilizers are truly essential to Mexico because of their significance to agricultural progress. In order to satisfy the food demands of a constantly increasing population, the scarce arable lands (around 8 million hectares in 1950) must be given the nitrogen they lack due both to the natural physical condition of the soil and to the effects of an irrational agricultural exploitation during many centuries. The magnitude of the problem is apparent in the fact that in 1947 the entire country consumed only 21,000 tons of fertilizers. In 1944, Guanos y Fertilizantes de México (financed by the Nacional Financiera) started its productive activities, although on a small scale, with its three plants, in Guadalajara, San Luis Potosí city, and the Federal District. A plant at Cuautitlán, State of Mexico, was founded in 1951, with a yearly production of 66,200 metric tons of ammonium sulphate, utilizing gas from the Poza Rica oilfields in Veracruz as raw material. This plant also was financed by the Nacional Financiera. The production of the Cuautitlán plant, one of the most perfect of its kind, is subject to such a large demand that plans for further expansion in fertilizer production, limited only by the difficulties in acquiring equipment, and, as in other cases, the scarce transportation facilities for the products, are more than justified.

Cotton Textiles.—Among the so-called light industries, the textile branch deserves special mention. Cotton is particularly significant because of its century-old tradition and its great importance in modern times, as well as because of the large number of workers employed and the pressing need of increasing production—especially of low cost fabrics, since several million inhabitants in the rural districts lack the most indispensable clothing and cannot satisfy that vital necessity due to their limited purchasing power. In 1945 the cotton textile factories manufactured products with a value of 676 million pesos; in 1950, 1,162 million. In the latter year, the raw material consumed had a value of 359 million pesos. The cotton textile industry employs 48,000 looms and 1,000,000 spindles. In 1950, of the 180 plants of this branch, only 10 were completely modern, 15 were modernized, 46 were established after 1925, and 109 before that date. Many managers, with their amortized plants and with difficulties in matters of credit, besides the numerous labor conflicts, are not in favor of the modernization of their equipment, as stimulated by the government. The workers, for their part, regard this technological progress with suspicion, believing, perhaps with good reason, that it will result in the unemployment of some 25,000 workers.

Until 1939, production greatly exceeded demand, and the managers, compelled by labor legislation and the impossibility of reducing working hours and wages, overstocked their warehouses and suffered losses which meant bankruptcy for some of them. World War II, with all the misery it brought to humanity, provided an advantageous and unexpected outlet for this industry. Stocks were easily disposed of, and all the productive capacity, including that of machines which might very well be considered museum pieces, was raised above theoretical output in order to satisfy the necessities of not only the Mexican population, deprived of imports, but also the demand of other countries whose markets were normally supplied by the great industrial countries then at war.

In this, as in other cases of eventual benefits brought about by the war, profits were not directed toward the most productive and beneficial uses for the country: the consumption of luxuries by those already profiting was increased; while those interested in modernizing found their efforts to acquire machinery and equipment obstructed by slow deliveries. A drift of huge profits toward investment in real estate took place, which forced prices upward. In the postwar period, after a severe decrease in exports of cotton fabrics due to the fact that foreign markets recovered their former providers, this branch of the textile industry went through a crisis which only the few modernized plants were in a condition to meet. To end this situation permanently, internal consumption must be increased with low-cost fabrics for the large masses of the population so poorly dressed and with such small incomes. The government is attending to this problem, which affects both the industry and the standard of living of numerous consumers, with a plan to increase the production of cheap fabrics, which was drastically curtailed by private manufacturers after 1940.

Shoes.—In regard to the great problem of the purchasing power of low-income classes, the shoe industry is somewhat similar to that of cotton fabrics. According to the 1940 census, of a total of 18,900,000 inhabitants questioned only 49 per cent wore shoes, 23 per cent wore *huaraches* (a sandal of popular use) and 28 per cent went barefoot. In 1950, production for this manufacturing sector was 67 million pesos, representing only 1.47 per cent of the total value of Mexican industrial production. For the more than 150 factories, some with completely modern equipment, there are nearly 1,000 workshops, most of them domestic, using in many cases rented machinery. To this we must add a large number of unregistered workshops, which contribute about

25 per cent to the total production. The output in general is low and consequently the workers' wages are also very meager. Not so retail prices, however, which are high because of the intervention of many distributors who carry their profits to the limit of consumers' purchasing power. The 10 million pairs of shoes produced in 1950 supplied only 33 per cent of the potential demand. Nevertheless, due to the fact that Mexico can supply the larger part of the raw materials needed by this industry, and because of the high qualifications of certain sectors of the manual labor force, and other favorable circumstances, this industry foresees a prosperous future.

General Prospects.—In general, Mexico undoubtedly has the necessary bases for an industrialization of respectable volume, and it can continue industrializing at the rate of the decade 1940–1950, despite certain financial difficulties, which can, however, be overcome. The first great problem is the need to channel new undertakings, with government participation, in such a way that convenient localization and high revenue may be attained, removing these enterprises or public services from any political interference that might disturb the normal development of the economy. The second problem is still more difficult. The industrialization process has been conceived as a way of improving the faulty distribution of the economically active population, with its persistently high percentage of agricultural workers. But if industrialization prefers high-capitalization industries, with supermechanized or even automatic installations, serious difficulties will be encountered by industry in attempting to absorb the labor force. Consequently, except in basic industries and public services, enterprises in which saving of capital is attained, in preference to those leading to saving of the labor force, would seem to fit the needs of Mexico's situation more fully.

FINANCIAL FACTORS

Profound changes have taken place in Mexico's economic and social life since 1925. On March 18 of that year the promulgation of the income tax law (effective in 1926) began the reform of the Mexican fiscal system and the establishment of the public revenue on a sound basis. The rehabilitation of the public credit was initiated in the same year, together with concern for a balanced budget, and during the next year (1926) the bases of agricultural credit were outlined, a most important factor in the attainment of the agrarian reform.

Financial Institutions.—*Banks.*—On Aug. 25, 1925, and on the basis of Article 28 of the Constitution of 1917, the Banco de México was founded. During its early life, the Banco de México went through an initial stage of participating, as did other private institutions, in the activities of a commercial bank, except for its unique privilege of coining, stabilizing the rate of exchange, and regulating interest rates. It was only when the Ley Monetaria (Monetary Law) of July 25, 1931 was passed, and other reforms, substantially ended on April 12, 1932, took effect, that this central institute started functioning as a bank of banks: establishing a rediscount system and regulating the amount of reserves to be held by private banks in the Banco de México as a guarantee for customers' deposits; aiming at the rationalization of credit; regulating the circulation of money; and defending the purchasing power of the peso in Mexico and abroad.

This banking reform was soon followed by the creation of a series of public banks to satisfy the specific needs of the economic development of Mexico: for agricultural credits, the Banco Nacional de Crédito Agrícola (1926)—now the Banco Nacional de Crédito Agrícola y Ganadero—and, later, the Banco Nacional de Crédito Ejidal (1935); for public works, the Banco Nacional Hipotecario y de Obras Públicas (1933); for industrial development, the Nacional Financiera (1934); for foreign commerce, the Banco Nacional de Comercio Exterior (1937); for the film industry, the Banco Nacional Cinematográfico (1941); for the development of cooperatives, the Banco Nacional de Fomento Cooperativo (1941); for small business, the Banco Nacional del Pequeño Comercio (1942); and, of lesser importance, for credits to members of the armed forces, the Banco Nacional del Ejército y la Armada (1947).

The Banco de México was an efficient collaborator with the government in the financing of public works, and made use of all its resources to check the inflation process as World War II accelerated the course of economic recovery from the depression of the 1930's, with the bank's cooperation. This central institute reduced to a minimum the speculations which were particularly active in raw materials and foodstuffs, and which were aggravated by "hot" or "refugee" money flying from countries at war. It handled with good judgment the eventual excess in the balance of payments during the war years, and channeled the effects of the deferred demand for capital goods, so necessary to a continuation of the country's industrialization.

Beyond the classical functions of the central bank's policies—the regulation of interest rates and open-market operations—the Banco de México realized that monetary maneuvers are only part of economic policies and therefore united its efforts to those of the government in the task of strengthening and increasing the economic power of the nation. For this purpose, the bank established a qualitative control on the total volume

of private banking credit, by raising reserve requirements and by establishing so-called *topes de cartera* (portfolio maximums). The object was to channel the credit activities of private banking houses, limiting those for commercial purposes and, at the same time, expanding those of a productive character, particularly in agriculture, industry, and basic utilities. As late as 1949 the composition of the portfolios of deposit banks, in the aggregate, was as follows: commercial credits, 48.3 per cent; industrial, 38.8 per cent; agricultural, 8.6 per cent; livestock credits, 3.9 per cent; mining, 0.4 per cent. On September 30 of that year all new deposits entrusted to banks in the future were neutralized; however, the disposal of 70 per cent of them for loans having a proved productive character was authorized. Later, the capacity of commercial banks to extend credit was curtailed, limiting it to ten times the capital, plus the reserves of the institution concerned.

Mexican banking institutions (Banco de México, national specialized institutions, and private institutions together) had total resources as follows: in 1945, 8,285.3 million pesos; 1946, 8,520 million; 1947, 8,981.5 million; 1948, 10,677.5 million; 1949, 12,385.3 million; and 1950, 15,660.4 million. Converted into dollars according to exchange rates in the respective years, the resources of the Mexican banking system were reduced from $1,700 million in 1945 to $1,400 million in 1949, surpassing the first figure only in 1950, when the resources amounted to $1,810 million.

The Banco de México had resources in 1945 of a value of 3,416 million pesos; declining in 1946 to 3,231.1 million and remaining at 3,271.2 million in 1947; but starting a rising curve in the following years: 1948, 3,813.1 million; 1949, 4,400.8 million; 1950, 5,620.7 million; and 1951, 5934.0 million. The second group (other national institutions) registered a constant increase—the most important in the entire system—in the course of those seven years (1945, 1,103.2 million pesos; 1951, 4,247.3 million). The same is true of the private institutions (1945, 3,765.5 million pesos; 1950, 6,796.8 million). In 1949 this last group led in resources, with 42 per cent of the total; followed by the Banco de México, with 35 per cent; leaving 23 per cent for other national institutions. The institutions of the system as a whole had on hand gold, silver, and foreign exchange with a value of 1,588.6 million pesos in 1949, and 2,725.4 million in 1951.

In 1949 a significant decrease was apparent in the net balances credited to Mexican banking houses by enterprises and individuals in the country; however, the system's balance in foreign money showed a very substantial increase. According to the report of the Banco de México for 1951 (published in 1952), the commercial banks, during that year, had raised the credit operations of 1950 by 24.1 per cent. During the same year (1951) the aggregate composition of the portfolios of commercial banks was as follows: 38 per cent, operations with industry; 19 per cent, agricultural credits; 36 per cent, commercial credits; 2 per cent, transportation credits; 5 per cent, consumer credits. These figures indicate an increase in the importance given to productive operations, and the favorable effect of the selective control measures of the Banco de México. However, a marked narrowness is apparent in the liquid assets of private enterprises; in 1952 private banks were softening the restrictive measures of the Mexican monetary authorities.

It is interesting to point out that the Banco de México, aside from its normal monetary and banking activities, plays a fundamentally important part in the economic development of Mexico. Other Latin American countries (Chile and Venezuela particularly) have limited their central banks to traditional activities, centralizing their objectives in regard to economic development—without any coordinating activities with the incentive programs of the government executive power—in special institutions, the *corporaciones de fomento* (development corporations). In Mexico, the central bank has taken over many of those functions, and has prevailed over the specialized public banking houses as a whole, which are organized in a system of autonomous institutions. The close connections for development purposes that the Banco de México has with the federal departments of the Treasury (Hacienda) and National Economy (Economía Nacional) must be emphasized, as also the activities of some of its own departments, in particular the Oficina de Investigaciones Industriales (Bureau of Industrial Investigations), its economic planning section. The bank also has very close relations with the Nacional Financiera in the field of industrial development.

Nacional Financiera.—The Nacional Financiera commenced its activities in June 1934. During its first stage (until 1940) it grew at a slow rate, but accumulated valuable experience. In 1937 it began turning its attention toward the stock market and issued its first bonds. In the following years it felt the blows of the unstable exchange situation, the nationalization of the petroleum industry (1938) and the beginning of World War II (1939). In 1940, legislation was passed, naming as the objectives of the Nacional Financiera:

> The vigilance and regulation of the security market, the stimulation of capital investments to create and expand productive enterprises and public utilities, and the representation, as fiduciary and agent, of the federal government and the municipal and state entities in regard to the issue and placement of stock.

In its second stage (1940–1947) important events took place. In 1941 the first participating certificates (*certificados de participación*) were issued to strengthen the position of government bonds and to begin the absorption of monetary excess in a period in which the flow of circulation was increasing constantly. These certificates, which allow their owners to participate in the enterprises financed by the Nacional Financiera, are in increasing demand by private persons because of high profit and redemption practically at sight.

The first industrial promotions were also begun in 1941—Cementos Guadalajara (cement) and Compañía Industrial de Atenquique (paper)—and the first credit ($30 million) was obtained from the Export-Import Bank in the United States. In 1942 the Altos Hornos de México (steel and plate) was established in Monclova, Coahuila, and in 1943 Guanos y Fertilizantes de México (fertilizers) and the Carbonífera Unida de Palau (coal mining) were instituted, among other incorporated promotions. At the beginning of the postwar period (second half of 1945) the Nacional Financiera devoted more than 72 million pesos to the Ferrocarriles Nacionales (railroads) and 68 million to Petróleos Mexicanos (petroleum). Between 1946 and 1947 five important sugar mills were established, in order to liquidate the national

deficit in the supply of that article. Also in 1946, the Comisión Nacional de Valores (National Securities Commission) was created to control the floating of capital stock and bond issues of new or enlarged corporations, and construction of Ayotla Textil (textiles), Industria Eléctrica de México (electrical equipment and household appliances) and other companies was started.

The third stage began in 1947 with the amendment of the law of 1940, raising the Nacional Financiera's capital from 20 million pesos to 100 million, turning it into an agent with power to negotiate long- and short-term credits from foreign, international, and private institutions, and establishing the bases of development which future promotions must follow. In 1947 Química Mexicana (chemicals), Viscosa Mexicana (rayon textiles), and other no less important companies were formed, and Sosa Texcoco (soda), Cementos Portland del Bajío (cement), Empacadora de Tampico (canning), and Vidriera Guadalupana (glass) started production. The International Bank for Reconstruction and Development in 1949 granted a credit of $34.1 million to develop electrification and $17.9 million to restore the railroads. In 1950 the study of a railroad plant was started and negotiations were begun with an Italian company for the assembly and manufacture of trucks in Mexico. In 1951 new promotions were companies for: coke and derivatives at Monclova, Coahuila; railroad car construction in Hidalgo; diesel trucks in Hidalgo; and two cellulose plants in Michoacán.

The issue of participating certificates was so successful that between 1941 and 1949 their total amount rose to 324 million pesos, and in 1950 it reached 713 million (in January 1952, 1,216 million). On Dec. 31, 1950 a new amendment was added to the legislation of 1940, and Export-Import Bank credits of $293.6 million were extended, of which $133 million had been already disposed of at the time; on Dec. 31, 1951 the authorized total was $382.6 million, of which $194.8 million had been disposed of. Between 1946 and 1950 the Nacional Financiera's total investment in industrial financing increased from 374 to 1,147 million pesos.

Public Finance.—In Mexico, as in the rest of the Latin American countries, the government has had a deep influence on economic development since 1940. In order to foster this progress, the Mexican government absorbed, through taxes, 11.4 per cent of the gross national product in 1939, 8.4 per cent in 1947, and 10.3 per cent in 1950 according to the economist Víctor Urquidi. Its effect is reflected more strongly in capitalization than in consumption: public entities, during the period 1946–1949, devoted from 31 per cent to 38 per cent of their expenses to the net formation of capital, either directly or as credits, guarantees, and other contributions. This represents from 29 per cent to 36 per cent of the net total capitalization of the country.

The net expenses of all forms of government were 753 million pesos in 1939, 2,352 million in 1946, and 5,834 million in 1951. In this last year, 4,158 million pesos were spent by the federal government; 330 million by the Federal District; 600 million by the states and territories; and 170 million by the *municipios* (municipalities)—the balance may be attributed to the expenses of various autonomous bodies. Investment expenses in 1951 amounted to 1,617.5 million pesos.

The budget results have been as follows—deficits or surpluses indicated by (+) or (—)—1936, +6.7 million pesos; 1946, —65 million; 1947, —401.2 million; 1948, —392.5 million; 1949, —49.1 million; 1950, —342.1 million; 1951, —558.5 million.

The main sources of revenue of the federal government have been: the income tax (which amounted to 7.5 per cent of the net receipts in 1939 and more than 20 per cent on an average from 1943 to 1951—25.7 per cent in the latter year); taxes on foreign trade, which have lost much of their importance as compared with other periods (34.5 per cent in 1939, 30 per cent in 1951); taxes on natural resources (44 million pesos or 7.6 per cent in 1939, and 287 million or 7.2 per cent in 1951); and taxes on industry and transportation (22.8 per cent in 1939, 6.1 per cent in 1951). Taxation on sales, excluding the sale of food and other essential products, however, became heavier—a tax on commercial incomes, instituted in 1948 to replace the stamp tax, furnishes the federal government with 1.8 per cent of net sales, and the states with 1.2 per cent. In 1948 an extra rate of 15 per cent ad valorem was established on exports to absorb 50 per cent of the exchange profits produced by the devaluation of the peso.

In 1940 an amendment to the income tax was introduced, placing an additional burden on excess profits in order to stimulate reinvestment of surpluses. In the first year (1940) this tax yielded 43.7 million pesos; in 1950, 60 million. The burden of the Mexican taxpayer is relatively light in comparison with that of people of other countries—even more so if the government's participation in economic development works is considered.

According to data compiled by the Secretaría de Bienes Nacionales (Department of National Property), which controls government purchases and payments to contractors, the finished projects which were supervised by that executive agency amounted, cumulatively, for the period from Jan. 1, 1947 to March 31, 1952, to 1,603.4 million pesos. Of this amount, 1,052.7 million pesos represented productive works of direct benefit (294.2 million in agriculture, and 758.5 million in communications), and 550.6 million represented projects for social welfare (of these 492.3 million for urban services, and 58.3 million for educational and assistance purposes). Commitments represented a total of 3,076.1 million pesos for projects, leaving therefore a balance of works in process valued at 1,472.7 million pesos.

The internal public debt was quoted on Dec. 31, 1950 as amounting to 2,079.5 million pesos, in circulation, with 1,284.9 million payable interest—a total, therefore, of 3,364.4 million pesos. The external public debt on the same date amounted to 230.6 million pesos, 15 million having been redeemed up to 1950. The balance due, therefore, amounts to 215.6 million pesos. The credit terms expire on Jan. 1, 1963 for guaranteed debts and the rest in 1968.

Of the total internal public debt in 1950, approximately 1,619 million pesos were held by the Banco de México, 180 million by the Nacional Financiera, and 279 million by other investors.

National Income.—Following the example given after 1940 by the more progressive countries (among them the Netherlands, Sweden, and the United States), Mexico has been concerned with studying the size and composition of its gross national product. It is evident that these large-scale (macroeconomic) data, although approximate,

can give a summarized idea of the progress achieved year after year, permit rough comparisons with other nations, and offer the bases, even though they be provisional, which indicate the trends of future economic progress. The four usual components of these types of studies—consumers', business enterprises', governmental, and foreign accounts—provide a pattern of the economic structure defined in broad outlines at the end of each fiscal period, even though such a picture may have a static character. If to this are added studies which bring one in contact with the income-expense relations (input-output, sources and allocations), and if, lastly, the net national income is found, Mexico will have achieved a great advance in statistical methods as compared with previous eras.

The national income at factor cost, according to the more reliable provisional figures, rose from 5,737 million pesos in 1939 to 15,551 million in 1944 and 37,816 million in 1950. For the same years, the gross national product at market prices (in which figure depreciation is included, subsidies are deducted, and indirect taxes are added) amounted respectively to 6,744 million, 17,317 million, and 43,299 million, all in pesos of the respective years. The report of the Banco de México shows a gross national product of 51,350 million pesos for 1952.

The account of consumers (considered as final distributors) shows, in salaries and nominal wages, on the income side, 1,792 million pesos in 1939, 3,719 million in 1944, and 7,491 million in 1949; and for the savings record, on the side of disposable income, the meager sums of 6.9 million, 175 million, and —186 million.

The consolidated account of the gross product of business enterprises shows, among other important entries, nominal distributed profits with a value of 1,067 million pesos in 1939, 5,007 million in 1944, and 8,454 million in 1949; and undistributed profits of 376 million, 508 million, and 3,116 million.

The federal government's gross investment was as follows: 247.7 million pesos (1939); 713.7 million (1944); 3,007.5 million (1951). Allocations to the four main categories of expenses were—agriculture and natural resources: 39.7 million pesos (1939); 124.8 million (1944); 595.9 million (1951); communications and transportation: 143.2 million (1939); 387.5 million (1944); 1,172.9 million (1951); electrical works and fuel: 27.0 million (1939); 60.4 million (1944); 687.9 million (1951); social and municipal works: 25.7 million (1939); 92.0 million (1944); 430.2 million (1951).

In the foreign account, in current transactions, the commercial balance in 1950 showed a deficit of $63.5 million (exports $533.8 million; imports $597.3 million); and in 1951 this deficit was raised to $353.1 million (exports $569.8 million; imports $922.9 million). The tourists' account, an important item in the "invisible" account, showed a net income of $162.5 million in 1950, and $175.1 million in 1951. Personal payments from abroad, particularly those received by workers in the United States, amounted to nearly $20 million in 1950, and $30 million in 1951.

In regard to the saving and investment account it is sufficient to state that the gross national savings (which balance with the gross national investments) amounted to 649 million pesos in 1939, 1,730 million in 1944, and 5,937 million in 1950.

Contributions of the main economic sectors to the national income in 1950 were, in nominal figures: wholesale and retail commerce, 30.9 per cent; agriculture, 14.1 per cent; manufacturing, 18.3 per cent; rents and interest, 6.0 per cent; private services, 7.4 per cent; government services, 5.1 per cent; mining and petroleum, 4.5 per cent; and transportation and communications, 4.3 per cent.

Taking the Mexican nation as a whole, and even making the elementary adjustments that have been made, the preceding data imply that the balance is satisfactory in regard to the past, and the general tendency for the future is clear and encouraging. But an impressive problem is immediately apparent if one is not influenced by the blurred per capita values. Carefully grouping the available data under a new light, the income derived from labor, in percentage of the gross national product, was 30.5 per cent in 1939, 23.7 per cent in 1944, and 23.8 per cent in 1950. On the other hand, the income (profits) derived from capital was 26.2 per cent in 1939, 37.6 per cent in 1944, and 41.4 per cent in 1950. In other words, in contrast with superdeveloped countries where labor participation in the gross national product increased at a fast rate after 1930, in Mexico the tendencies are moving in the opposite direction. If attention is turned to one of the first theses of the present examination—the swift demographic growth of Mexico's population—one finds, clearly defined, a task which cannot be delayed and an ultimate goal for future administrations of the country: to invert the terms of the problem, arbitrating solutions by which economic development may be attained without as costly a sacrifice by the lower economic classes of the population. To reach this objective, without at the same time decreasing the investors' legitimate profits—but on the contrary, raising them, not because of the increased consumption but as a result of its extension to vast potential zones—is undoubtedly the worthiest project for accomplishment by the Mexican government, with the help of all of the country's productive factors.

FOREIGN TRADE

Since the end of World War I Mexico's trade relations, and its trends, have reflected the importance of the United States as the primary world creditor. That country's capacity of production introduced very important changes in the volume and composition of Mexican foreign trade. In 1935-1939 Europe furnished Mexico with only

a third of Mexican imports, Germany and the United Kingdom being the main exporters; Mexico obtained six tenths of its imports from the United States, which in turn purchased two thirds of Mexican exports during the same period. Europe received only one fourth of Mexican exports.

After 1940, during World War II, the United States became the only important market for Mexican imports and exports, although Mexican products were in demand in other countries in Latin America, and even in South Africa and southern Asia. In the peak year, 1943, imports from and exports to the United States were 88.5 per cent and 87 per cent, respectively, of the Mexican total.

The year 1948 began a return to more normal relations. The highly developed nations recovered their traditional markets, but on the other hand Mexico intensified the importation of capital goods, durable goods, and raw materials, so necessary for the industrialization programs. These included equipment for manufactures and assembly plants, railroad equipment, cellulose and nylon. Mexican imports from Latin America fell to prewar levels (2.5 per cent); even lower in 1952 (0.9 per cent), when Canada furnished 2.5 per cent of Mexican imports. Europe advanced to 13 per cent of Mexican imports, at the expense of the United States, imports from which were reduced to some 80 per cent.

In 1951 Mexican exports were distributed as follows: United States, 70 per cent; Europe, 17 per cent; Latin America, 7 per cent; rest of the world, 6 per cent.

MODERN ECONOMIC POLICY

The Mexican social revolution began Nov. 20, 1910, with the uprising in Chihuahua. The armed struggle lasted seven years. It accounted for thousands of lives, and destroyed, mainly in the rural areas, part of the riches that had been accumulated during the 30 peaceful years of the rule of President Porfirio Díaz. Nevertheless, everything considered, the bitter fighting opened the way for the profound changes that were carried out in the economic structure of the country, as well as in its political organization and legal institutions.

The foundations of modern Mexican political economy were laid during the years 1925 and 1926, when Plutarco Elías Calles was president; this is the same policy that has been continued into 1953 and which will, most likely, go on in the near future. It has been improved with the years. No doubt the continuity of purpose for nearly 30 years and the desire of each new government to improve on the achievements of its predecessors have played a very important part in the economic advance of the nation. This would explain the progress achieved in the economy and the confidence which is noticeable in wide sectors of the population.

Legal Bases.—The new constitution, promulgated Feb. 5, 1917, contains Articles 27 and 123, which were aimed at satisfying popular demand for reform in the social and economic fields. Both articles have since had boundless repercussions on the economic development of Mexico.

Article 27 sets forth the following principles:

The rights of ownership of the land and water comprised within the boundaries of the national territory belong primarily to the nation, which has had and has the right of transferring their control to private individuals, thus giving rise to private property.

Expropriations can be carried out only for reasons of public utility and through indemnity.

The nation shall always have the right to impose on private property regulations in the public interest, as well as the right to control the exploitation of any natural elements that can be so exploited, in order to distribute public wealth on an equable basis and to care for its conservation. To this end, whatever regulations are deemed necessary will be issued for the fragmentation of *latifundia* [large estates]; for the development of private property; for the creation of new agricultural centers enjoying the tenure of indispensable land and water; for the encouragement of agriculture and to avoid the destruction of natural elements and whatever damage property may suffer to the detriment of society. Villages, ranches, and communities lacking land and water supply, or not having a sufficient amount for the needs of the community, shall have a right to being endowed with them, taking them from neighboring properties, but always respecting small holdings.

The article later continues:

The acquisition of the private property necessary to achieve the ends stated, shall be considered [as having been made on the basis] of public utility.

Regarding ownership of the subsoil, the following paragraph from Article 27 states:

The nation shall have direct control of all minerals or matter found in seams, layers, concentrations, or veins forming deposits the nature of which may be different from that of the components of the soil, such as minerals from which metals and metalloids used in industry are extracted, veins of precious stones, salt mines and also salt ponds formed directly by sea water, the products derived from the breaking up of rocks, when their exploitation makes underground working necessary, phosphates that can be used as fertilizers, solid mineral fuels, petroleum, and all carbohydrates in liquid or gaseous form.

Article 123 concerns labor laws. Among other provisions, it sets forth the following, which are the most important:

1. An eight-hour working day.
2. Children under 12 years are forbidden to work.
3. A weekly day of rest.
4. Protection to women about to become mothers, who must cease to do work requiring considerable physical effort three months before childbirth, and will also enjoy one full month's compulsory rest after childbirth; receiving their full pay and keeping their job, with every right that they shall have acquired as stated in their contract.
5. The minimum wage shall be sufficient to provide for the normal needs of the worker's life, education, and legitimate pleasures of the man considered the head of the family.
6. The employer is required to provide schools for the worker's children when the industrial premises are situated at a considerable distance from any populated area.
7. Employers are held to be responsible in certain cases of occupational accidents and sickness.
8. The right is granted for both employers and employees to organize to defend their interests; the former are granted the right to close their plants, the latter the right to strike.

Application.—These two constitutional articles have had a far-reaching influence on Mexico's economic policy since 1917. The agrarian reform has been steadily changing the old system of land exploitation through large holdings, found in the haciendas that had been in existence since colonial times. Article 27 has been the basis on which the breaking up of these large estates has been carried out, thus giving rise to the communal landholdings of the Indian villages and also to

small private property. In altering the organization of private property in rural areas, it has also been found necessary to carry out certain changes in the agricultural and cattle-raising policy of the whole nation, as will be described below.

Article 27 has also had a certain influence on mining laws and on government policy concerning petroleum. The mining companies, mostly British- or United States-controlled, had never raised any international problems for the Mexican government; on the other hand, the oil companies had always been the cause of disagreements, sometimes far-reaching, between Mexico and the other two countries. Of the capital invested in oil in Mexico at the time of expropriation, United States firms held approximately 38 per cent, British firms 60 per cent, and Mexican firms 2 per cent. The expropriation of the holdings of these firms in March 1938 was based on Article 27.

Article 123 was regulated by rules set forth in the Ley del Trabajo (Labor Law) of 1929. This law and the before-mentioned article together regulate economic and social relations between workers and employers.

Land Reform.—There was no clearly defined economic policy in the years from 1917 to 1924, under presidents Venustiano Carranza, Adolfo de la Huerta, and Álvaro Obregón. The only sign of an economic policy was the distribution of land to the villages. The peace had not yet been consolidated; those were years of reconstruction, of discussion of new plans aiming at transforming the country's organization.

The distribution of land could not be put off, since there was a general and urgent demand from the agricultural masses; without it, no lasting peace would have been possible, in spite of every Mexican's anxiety to be done with fighting. According to the census of 1910 there were in Mexico only 840 hacienda-owners, who—it was estimated—owned among them three fourths of the national territory; while, according to the same census, there were over 3 million agricultural workers without land. It thus became imperative to start distribution right away, without waiting to draw up a well-thought-out technical plan. The crying need of land had been the main cause of the revolution.

From early in 1916 until Dec. 31, 1924, 3,292,332 acres of land were distributed among various agricultural communities, with benefits accruing to 178,829 families. But it must be pointed out that they were given land which in many cases was of poor quality, without machinery, without fertilizers, and without facilities for obtaining credit. Naturally enough, the results were not very satisfactory; indeed, in some cases they were completely negative.

Credit.—In the years 1925 to 1926, it was clearly seen that the agricultural problem could not be satisfactorily solved if the government were content with merely giving land to the people, who were applying for it in ever-increasing numbers. It was at the same time necessary to grant them credit at long, medium, and short terms; long-term credit, in order to enable them to build irrigation ditches, storehouses for produce, and the like; medium-term, so that they would be able to buy agricultural machinery, such as plows, tractors, and trucks; and short-term, to make it possible for them to buy seeds and to live before the harvest. For these purposes the Banco Nacional de Crédito Agrícola (National Agricultural Credit Bank) was founded March 1, 1926; followed shortly after by the founding of small credit institutions, called *bancos agrícolas ejidales,* to provide credit for communal village lands (*ejidos*). By 1935 these small banks had been closed. They had failed, partly because they operated with very small capital. But the Banco Nacional de Crédito Ejidal was founded in their stead in the same year, 1935, and became one of the two great credit organizations which work with capital supplied by the federal government. The Banco Nacional de Crédito, Agrícola had, up to Dec. 31, 1950, granted credit to a value of 1,247 million pesos, of which it had recovered 936 million. Its capital was then 213 million. As for the Banco Nacional de Crédito Ejidal, it had on the same date a capital of 250 million pesos, had loaned 1,637 million, and the recovery amounted to 1,314 million. The federal government constantly supplies the banks with new funds.

More recently some private banking institutions have also provided funds on credit for agriculture, mostly in small amounts; among them the Banco Nacional de México, founded in 1884.

But in spite of governmental policy, it has been impossible to meet in full the demand of the nation's agriculture for credit. There are still many unsatisfied needs, which can only be attended to very slowly.

Irrigation.—The year 1926 also saw the beginning of extensive irrigation work aimed at reclaiming new lands for agricultural uses. This program has progressed uninterruptedly and continues on an increasing scale, as can be seen from the work started at the end of 1947 on the Papaloápan (Papaloápam) River in Veracruz and the Tepalcatepec in Michoacán. When the Papaloápan project is finished, Mexico will have one of the largest irrigation systems in the world.

Education.—It was also in 1926 that the first agricultural schools were organized. Their purpose was to teach agricultural workers and their children new methods of cultivation. There were 15 agricultural schools in the country in 1952, apart from the Escuela Nacional de Agricultura (National School of Agriculture) at Chapingo, State of Mexico, where a seven-year course is given, leading to the degree of agricultural engineer. The other 15 have less comprehensive plans of study, for a total of 5,000 students, who are to play an important role in the modernization of Mexican rural areas.

Minerals.—It can be said that the government has given almost complete freedom to mining firms, apart from its intervention through a system of taxation and its subsidies to cooperatives that continue to exploit impoverished properties, in order to keep such sources of employment operating as far as possible.

But the case of petroleum is entirely different. After 1917 the Mexican government had many serious, sometimes extremely serious, difficulties with the oil companies. About the middle of 1937 after a week-long strike which seriously affected the country's economy, the oil workers submitted to the companies certain demands which the latter refused to meet, arguing that their resources did not make such concessions possible. The workers demanded larger salaries and the improvement of social services, such as medical attention, hospitalization, indemnity in case of occupational accidents, and more holidays with pay. The workers' demands meant an increase in expenditure of 90 million pesos and the companies were

ready to meet them to an extent of only 13.5 million. Thus the conflict was not easy to solve.

The usual procedure in dealing with such conflicts is for the labor authorities to appoint three experts who draw up a report on the financial situation of the company or companies, as well as recommendations expressing their opinion as to the most suitable way to end the dispute. Experts were, therefore, appointed. They drew up their report and recommendations within the appointed time, stating that the oil companies could well afford to increase their expenses by 26.5 million pesos without any undue strain. The labor authorities, after hearing the objections that employers as well as employees raised to the experts' report, gave their final decision, which was in agreement with the recommendations of the experts. The companies did not agree and appealed to the Supreme Court. The court confirmed the decision of the labor authorities. The companies, however, refused to accept the decision of the Supreme Court and took a rebellious attitude. It was then, on March 18, 1938 that the government decreed their expropriation.

The first years of Petróleos Mexicanos—this was the name of the official firm which took over the companies' properties—were difficult, years spent in organizing; but as of 1953 it could be said that the Mexican oil industry was firmly established and was progressing from day to day. A new oil pipeline was built from Poza Rica to Salamanca, where a new refinery was completed in 1951, with an output of 30,000 barrels daily; hundreds of new wells have been drilled and new fields discovered. Oil production, which under the foreign companies totaled 119 million barrels in the three years 1934 to 1936, increased to 215 million barrels from 1949 to 1951 inclusive. American companies have already received full payment for the property expropriated, some $35 million; the Anglo-Dutch company (Royal Dutch Shell) had been paid $43 million as of 1952; the balance of $44 million to be liquidated by the payment of annual installments until 1962.

Transportation.—The building of motor roads was started during Gen. Plutarco Elías Calles' term of office (1924–1928); and has continued uninterruptedly. The road-building policy has tried to fulfill two aims: to join production centers with consumers, and to favor the tourist trade.

Much less has been done to develop the railways. Efforts are being made to modernize them and to put them in a position to meet the growing demand for transport efficiently, but this requires the investment of considerable sums of money. See also the section *Transportation and Communications.*

Industrialization.—A policy favoring the establishment of new industry was initiated in 1939–1940, during the last two years of President Lázaro Cárdenas' term of office. Facilities were given by granting exemption from the payment of taxes for a few years and also loans on a long-term basis. The Nacional Financiera (see below) was important in this financing. Industrialization gained a new impetus during World War II, and an even greater one after 1946. During the war there was a great lack of certain goods, sometimes indispensable ones, which had previously been easily imported from foreign countries, especially the United States. This influenced Mexicans to push on with the creation of new industries and to strengthen those already in existence.

However, Mexican statesmen, as well as economists, know full well that their country will never be able to equal the United States in industrial potentialities. But they also know that Mexico has a very good chance of becoming industrially powerful; among other reasons because it has iron, coal, oil, ample possibilities of enlarging its electric resources, and a good number of other raw materials. Moreover, economists as well as statesmen realize that industrialization will help to raise the standard of living of an important sector of the community.

Tariffs.—Mexico has always been a protectionist country, sometimes more and sometimes less, according to the circumstances. After 1940 economic policy concerning foreign trade was based openly on protection for new industries and on the opening up of new sources of employment, as in the case of automobile assembly plants. The customs duty payable on unassembled cars is very low, while that on assembled motor cars is extremely high. There is an organization, the Comisión de Aranceles (Tariff Commission), whose job it is to study and recommend to the Treasury Department (Secretaría de Hacienda y Crédito Público) any necessary changes in import and export tariffs. This commission is made up of representatives from several federal departments, and from the Confederation of Chambers of Commerce and Industry. Certain tariffs are raised on occasion, following Treasury requirements. This, of course, does not happen often.

Financial Institutions.—The Banco de México, being the central bank, is mainly concerned with loans to other banks, the issue of paper currency, the control of currency circulation and foreign exchange, and is the financial agent of the federal government. The Banco de México was founded by law on Aug. 25, 1925 and opened for business on September 1 of that year.

Besides the Banco de México, and the Banco Nacional de Crédito Agrícola and the Banco Nacional de Crédito Ejidal (described above), there are other banking institutions most of whose stock is owned by the federal government. Among these, the Nacional Financiera, the Banco Hipotecario Urbano y de Obras Públicas, and the Banco Nacional de Comercio Exterior deserve mention.

The Nacional Financiera has become very important since about 1939, mainly because of its intervention in financing new industries. It owns the greater part of the stock in many of them. Its policy consists in contributing whatever capital it may be necessary to add to private investments to facilitate the creation of new industry that will play a useful part in the economic progress of the nation. As soon as these industrial concerns are fully developed, however, the Nacional Financiera tries to get rid of its stock by sale to private investors. Sometimes this institution issues bonds to bearer to be placed among various investors. These bonds return an annual interest of six or seven per cent, as for instance, *certificados de participación* (participation certificates) and *bonos de caminos* (highway bonds). It also buys on the stock exchange.

The Banco Nacional Hipotecario Urbano y de Obras Públicas (National Urban and Public Works Hypothecary Bank) is concerned mainly with loans to states and *municipios* (municipalities) for the construction of sewage facilities and waterworks. The Banco Nacional de Comercio Exterior (National Foreign Trade Bank) con-

trols, among other things, certain business operations carried out between Mexico and foreign countries.

There are, besides, a number of private credit institutions that help in the economic development of the country and sometimes make considerable profits. Most of them are banks doing only deposit and discount operations, and they issue loans usually on a short-term basis. They have grown considerably in number since 1940; both because banking has turned out to be very lucrative in Mexico, and because of the facilities granted by the Ley General de Instituciones de Crédito (General Law for Banking Institutions), in 1937 and thereafter, and the stimulating policy of the Treasury Department. Banking policy has consisted in authorizing the formation of new banking concerns, always in accordance with the law and wisely defined to avoid duplication. It is the job of an official institution, the Comisión Nacional Bancaria (National Banking Commission), to keep a constant watch over all banking concerns and so to secure the public interest.

Taxation and Expenditures.—In the 1920's the federal government depended on mining and petroleum taxation for a considerable part of its revenue. Such taxation has steadily been losing importance since 1942. The income tax, which became effective for the first time in Mexico in 1926, now accounts for most of such income and grows constantly. A comparison of the years 1940 and 1951 shows that the income of the federal treasury, reckoned in dollars, increased fivefold; the increase of production and the development of business, as well as an improved budgeting technique accounting for the increment.

A fact of singular importance, which reveals a certain aspect of the government's economic policy, can be observed in its expenditure. The War Department headed the list of public expenditure in 1925, while in 1950, for instance, communications came first, followed by capital investments; education came third; waterworks fourth; followed by national defense in fifth place.

The most serious problem of Mexico as regards contemporary economic policy is the achievement of a better distribution of the national income, since the mass of the people has in no way enjoyed the undeniable overall increase of such income.

7. LABOR MOVEMENT. The lack of an industrial movement during the 19th century retarded the growth of labor unions in Mexico during that period. Few labor groups were formed, the most important being the Gran Círculo de Obreros (Grand Circle of Workers), founded in 1876.

Labor activity increased up to 1884, when it was effectively suppressed by Porfirio Díaz. From 1865 to 1877 there was a period of labor unrest with many strikes.

In 1906 the Círculo de Obreros Libres (Circle of Free Workers) was founded, and a series of strikes was organized by this group among textile workers to obtain an eight-hour day and minimum wage levels, but these strikes were broken in the same year.

During the years 1907 to 1911 new organizations made their appearance in Mexico City. The most important of these was the linotypist union, Unión Linotipográfica de la República Mexicana. The Casa del Obrero Mundial (World Worker's House), founded in Mexico City in 1912, was the first labor organization to receive government backing. It was supported by President Venustiano Carranza's government, and during the revolution organized the so-called red battalions which fought on the side of that government.

CROM.—In 1918 dissident elements of the Casa del Obrero Mundial founded the Confederación Regional Obrera Mexicana (Regional Confederation of Mexican Workers) and affiliated themselves with the Amsterdam Syndicalist Federation. The leader of this group was Luis Morones, who later served under President Plutarco Elías Calles as minister of commerce, industry and labor. Morones, called "Czar of Labor" by the American writer Lesley Byrd Simpson, and his followers were the founders of Mexican labor *liderismo*, an absolute domination of union and members by the leaders; strikes often being called or stopped according to their personal interests. Morones and the CROM's central governing committee, the Grupo Acción, attained the peak of their power during the Calles administration.

The CROM had an initial membership of 7,000 members. By 1927 it counted 2,500,000 members in its ranks. During the years 1924 to 1926 it was affiliated with 76 national organizations, 106 unions located in the Federal District, and with about 1,000 syndicalist groups and 1,500 peasant unions scattered throughout Mexico. Without a doubt, the CROM was the most important labor body in Mexican history. In 1936 it became a member of the London World Syndicalist Federation.

CTM.—The speed with which the CROM grew was matched by the rapidity with which it disintegrated, a decline due to its submissiveness to the government and loss of zeal. The groups that broke off met in a unification congress in 1936, which resulted in the organization known as the Confederación de Trabajadores Mexicanos (Confederation of Mexican Workers). The CTM had a starting membership of 20,000 workers. By 1940 its membership had increased to well over a million. This powerful labor group has as its motto, "Toward a Classless Society," and had as its leader the Soviet sympathizer Vicente Lombardo Toledano, who in 1936 also became the leader of a new international labor group, the Confederación de Trabajadores de la América Latina (Latin American Workers' Confederation).

The CTM suffered a severe drop in membership in 1942, which was in great part due to the communistic policies followed by its leaders. The loss of membership, however, continued even after 1949, when it broke with the Communist elements with which it was infiltrated.

Newer Unions.—Vicente Lombardo Toledano, who was ousted as leader of the CTM in 1949, organized a new labor body, known as the

Unión General de Obreros y Campesinos de México (General Workers and Peasants Union of Mexico) in the same year.

Luis Morones organized the Proletaria Nacional (National Proletariat) in 1952, which was closely linked with the *Peronista* movement emanating from Argentina and represented by the Comisión para la Unidad Obrera de Ibero América (Commission for Ibero-American Labor Unity). Three minor unions fused to form the Proletaria Nacional: the Confederación Nacional Proletaria (National Proletarian Confederation) of anarchist-syndicalist tendencies; the Confederación Nacional de Trabajo (National Labor Confederation) of communistic tendencies; and the Confederación de Obreros y Campesinos de México (Confederation of Workers and Peasants of Mexico). Prior to the merging of these three groups there were in Mexico approximately 15 national and central unions, without any link among themselves. By 1950 there were 165 federations, 20 worker syndical confederations, an employers syndical confederation, and over 8,200 local unions of all types, with more than half a million workers.

Legislation.—The Congress of Queretaro incorporated "liberty of professional association" in the Constitution of 1917. In 1929 Congress passed the Ley del Trabajo (Labor Law), establishing the Special Minimum Wage Commission, conciliation and arbitration boards, and other labor bodies. Unions were declared "public corporations subject to industrial law" by the Supreme Court in 1938.

Strikes.—The report of the National Workers Confederation Committee of the CTM, published in Mexico City in April 1938, gives the strike statistics in the following table:

Year	Strikes	Year	Strikes
1920	173	1928	7
1921	310	1929	14
1922	197	1930	15
1923	146	1931	21
1924	136	1932	56
1925	51	1933	13
1926	23	1934	202
1927	16	1935	642
		1936	659

No information is available on the numbers of strikers participating. As will be seen, the number of strikes gradually declined after 1921, the year in which the revolution may be said to have been consolidated by President Alvaro Obregón, until the effects of the great economic depression were felt in Mexico during the administration of Lázaro Cárdenas. No information is available for the years 1937–1940.

The *Compendio estadístico* (1951) of the Dirección General de Estadística gives the information in the following table.

Year	Strikes	Strikers	Year	Strikes	Strikers
1941	142	12,892	1944	887	165,744
1942	98	13,643	1945	220	48,055
1943	766	81,557	1946	207	10,202

The labor conciliation boards settled 87,327 labor-management conflicts in 1941–1946.

8. TRANSPORTATION AND COMMUNICATIONS. Mexican transportation reflects the difficult conditions under which the system was constructed. From 600 kilometers (1 km. equals .62 statute mile) of railways in 1875, the total increased to 22,300 km. in 1949 and to 23,319 km. in 1950. By 1950 highways totaled 21,968 km., airline services extended over 159,605 km. (65,264 km. on regular schedules), and there were 2,028 km. of oil pipelines plus 1,032 km. of gas pipelines. Ocean transport accented the importance of the oil industry: in 1950, 9 steamers (16,362 net tons) flew the Mexican flag, together with 12,000 net tons of small craft and some 230,000 deadweight tons of ships connected with the petroleum industry, of which 19 were tankers.

The initial planning of land transport routes conformed to no strong national or logical criteria. During the Díaz regime (1877–1911) communication lines were developed to facilitate export of raw materials via ports and borders, and to supply the national capital with imported articles. This was reflected in the predominance of foreign investment in railroads, in correlation with investments in mining and agriculture. Not until 1907 was the Ferrocarriles Nacionales de México created, with the government as majority participant. The nationalization of railways occurred in 1937 under President Cárdenas in hope of alleviating the shortage of rail facilities (11.9 km. of track per 1,000 sq. km. of area). The expansion of railway facilities has been handicapped by deficit conditions, by deterioration of fixed equipment and rolling stock, by high wage budgets for a multitude of low-wage workers, and the heavy expense of renting numerous passenger and freight cars from the United States.

During the administrations (1940–1952) of presidents Manuel Ávila Camacho and Miguel Alemán appropriations for the Secretaría de Comunicaciones y Obras Públicas (Department of Communications and Public Works) consistently exceeded those for any other department. Trunkline communications have been improved and augmented, and new feeder lines have incorporated into Mexican economic and cultural life many areas hitherto isolated.

Motor vehicles numbered 288,368 as of January 1, 1950; about half of these were private passenger cars, the remainder were trucks, buses, and taxicabs. By January 1951, 285,600 telephones were in service; slightly over half of these were in Mexico City, and almost all of them were operated by private companies.

The postal service has modern equipment; there were 4,043 post offices with 14,499 employees in 1951, and they handled 610 million pieces of mail, including about seven tons of letters per day.

Air Transport.—Between 1930 and 1949 the total number of kilometers flown by commercial aviation increased nearly tenfold (from 4 million to 37.8 million km.). The number of passengers carried in 1930 was 21,000; in 1951 the corresponding figure was 1,128,385. In 1950 there were 38 airports and 165 smaller landing fields in Mexico; by 1952, public investment in airport construction and repair amounted to 94 million pesos. From 1940–1948 private companies invested 132

million pesos. New airports completed in 1951 included those at Campeche and León, and one of the most beautiful and efficient airports in Mexico, that of Guadalajara. The 29 domestic and 6 international airlines serve virtually every town and city of importance. Air cargo includes agricultural produce, industrial goods, sea foods, even jungle products, such as chicle. There are three schools of civil aeronautics; one, the Cinco de Mayo in Puebla, is a dependency of the Secretaría de Comunicaciones y Obras Públicas.

Railroads.—Twenty-one railroad companies operating some 1,449 miles of track were registered in 1948 with the Secretaría de Comunicaciones y Obras Públicas; the balance of about 22,300 km. being government-operated. In 1940 work began on the Ferrocarril del Sureste (Southeastern Railroad), which crosses innumerable rivers and marshlands and connects the Peninsula of Yucatán with the national network; this was completed in 1950. On the opposite side of the country the costly Ferrocarril Sonora–Baja California, which crosses the desert called Desierto de Altar and links Lower California with the rest of the country, was also completed. In July 1950, construction was begun on the Durango-Mazatlán line; the importance of this project is evident in the expectation that it will benefit 30 per cent of Mexico's population. Over 11 miles of tunnels and more than 1,000 meters of bridging will be required on this line. A line from Mexico City to Tuxpan, Veracruz, was under construction in 1952, while a new modern passenger terminal and a new freight terminal were being completed in Mexico City. A rational plan of laying heavier tracks was adopted after 1946 to facilitate higher speeds and the carrying of heavier loads; diesel units have been acquired, and a plant to manufacture railway cars is being promoted.

Highways.—The creation, in 1925, of the Comisión Nacional de Caminos provided the first positive impulse, reinforced later by the administrative efforts of the Department of Communications and Public Works, which undertook an ambitious plan of highway construction in cooperation with various state governments; under President Alemán annual appropriations for this purpose averaged 300 million pesos. From 1925 to 1940, the yearly average of construction was about 664 km. (total: 9,968 km.) and this average rose to 1,333 km. per year between 1941 and 1949. Approximately 22,000 km. were constructed up to 1949; 57 per cent were paved, 33 per cent "improved," and 10 per cent were dirt roads. During the 25 years, 2,135 million pesos were expended, of which nine tenths came from the federal government.

By 1951 main trunk routes were undertaken to tap the vast regions of Yucatán and Lower California. Construction of the Carretera Internacional del Noroeste (Northwest International Highway) from Guadalajara, Jalisco, to Nogales, Sonora (1,069 miles), was pushed intensively. At Mazatlán, this highway will connect with the Matamoros, Tamaulipas-Mazatlán, Sinaloa highway.

The year 1952 saw the completion of the 728-mile coast-to-coast road from Tampico, Tamaulipas, to Barra de Natividad, Jalisco, except for the paving of 170 miles of the section Barra de Natividad-Acatlán. Construction was in progress on the Transisthmus highway from Coatzacoalcos, Veracruz, to Salina Cruz, Oaxaca. The Mexico City-Cuernavaca superhighway, inaugurated in 1952, is a 22-meter boulevard; each of the double lanes is 7.5 meters wide. Entrance boulevards 30 to 40 meters wide had been completed for the Mexico City-Acapulco and the Guadalajara-Chapala highways.

Other completed roads include the 1,327-mile Mexico City-Ciudad Juárez route, the 760-mile Mexico City-Nuevo Laredo route, and the Carretera Cristóbal Colón (846 miles) which links the capital with Ciudad Cuauhtémoc, Chiapas, on the Guatemala border. The opening of the latter constituted a milestone in Mexican highway development, for it completed Mexico's part of the Pan American Highway and made it possible to travel on good roads from Fairbanks, Alaska, to Guatemala.

Local Roads.—The federal government's extensive program of building local roads, designed to bring a majority of the small towns and agricultural areas within range of first-class trunk highways, began with creation of a new bureau within the Department of Communications and Public Works to develop this type of road. Automobile assembling firms and tire manufacturers offered to pay an additional tax of 10 per cent, and thus financed these roads in part. A presidential decree of Oct. 12, 1949 inaugurated a plan of dividing the cost of local roads equally between the federal government, state governments, and private enterprise. Construction allocations and priorities depend upon the anticipated volume and type of traffic. Some of these roads are constructed with an absolute minimum of investment, but are designed to facilitate improvement as traffic may require. In 1952, 273 miles of such roads had been completed, and 1,324 additional miles were under construction. Some of these are gravel roads four meters wide, others are asphalt roads up to nine meters wide.

Telecommunications.—Telegraph services have been modernized by radio relay stations, multiplex transmission and printing, and other devices for simultaneous transmission of several messages on the same line. The telegraph system functions in liaison with urban and long-distance telephone systems. No state capital or city of importance lacks long-distance telephone service. There are about 214 radio broadcasting stations, and four television stations in 1952.

Pipelines.—In 1950 the daily transport capacity of oil pipelines was 817,000 barrels of crude petroleum and other products. Between 1938 and 1950, five gas pipelines totaling 447 km. in length and with a daily carrying capacity of 410 million cubic feet were constructed. Another pipeline from Monterrey to Torreón (340 km.; daily capacity, 100 million cu. ft.) was under construction in 1952.

Harbors.—There are ten harbors on the Pacific coast and twelve on the Gulf of Mexico. Of the former, Guaymas; Yavaros, Sonora; Mazatlán; Manzanillo; and Acapulco are natural harbors; on the east coast there is but one natural harbor: Ciudad del Carmen. The only breakwaters are at Veracruz, Tampico, Coatzacoalcos, and Salina Cruz.

The decreasing relative importance of sea and rail transport on the one hand and the increasing importance of air and highway transport on the other carries implications for Mexico's efforts to modernize and extend both fixed and mobile equipment. Coordination and integration of these systems depend on the skill with which

government agencies estimate the services that each factor can render most effectively in relation to the needs of the national economy.

Professor of Economics, Universidad Nacional de México; Head, Department of Economics, Mexico City College; Economic Adviser, Banco de México.

9. THE PRESS. The stormy history of Mexico during most of the 19th century is reflected in its journalism; political journalism was the order of the day, as were colorful names.

The first newspaper of consequence to be printed in Mexico was a *Gaceta de México* (*Mexico Gazette*), founded in 1805 by Juan Villaurrutia, a court judge, and suspended in the same year. However, a great number of pamphlets, leaflets, and journals were published soon after, under the freedom of the press briefly granted by the Spanish Constitution of 1812. Among the many publications circulating in Mexico at the time, the most outstanding were *El Pensador Mexicano* (*The Mexican Thinker*) published by Fernández de Lizardi and *El Juguetillo* (*The Plaything*) published by Carlos María Bustamante; both in Mexico City. In the same year, however, Viceroy Francisco Javier Venegas, under the pretext that the newspapers were abusing the liberty of the press granted under the constitution, suspended these and fourteen other publications. This resulted in a flood of illegal pamphlets and leaflets, which were distributed throughout Mexico.

The burning issue of the times was the independence of Mexico from Spain. Among the publications favoring independence in 1811–1812 were *El Despertador Mexicano* (*The Mexican Awakener*), published at Guadalajara as a result of Miguel Hidalgo's entry into that city; *El Ilustrador Mexicano* (*The Mexican Illustrator*), published at Zitácuaro by Andrés Quintana Roo; *El Despertador Michoacano* (*The Michoacano Awakener*), at Valladolid (now Morelia); *El Correo Americano del Sur* (*The South American Courier*) at Oaxaca, and *El Mexicano Independiente* (*The Mexican Independent*) published by José María Morelos at Iguala. The Spaniards countered by publishing the newspapers *El Fenix* (*The Phoenix*), *El Ateneo* (*The Athenaeum*), and *El Español* (*The Spaniard*); all at Mexico City, 1811–1812.

After the Independence.—After Agustín de Iturbide's army had entered Mexico City in 1821, Carlos María Bustamante published the *Avispa de Chilpancingo* (*Chilpancingo Wasp*), with other minor publications making their appearance. When Iturbide had proclaimed himself emperor the *Gaceta de México* mentioned above became the *Gaceta Imperial.* Iturbide suspended those newspapers which directed attacks against his government and it was not until his downfall in 1823 that newspaper publishing gained new force. In 1824 the Freemasons belonging to the Scottish rite, and conservative in policy, founded *El Aguila Mexicano* (*The Mexican Eagle*), while those of the York rite, liberal in policy, founded *El Observador* (*The Observer*) in the same year, together with the *Correo de la Federación* (*Federation Courier*), and in 1825, the *Amigo del Pueblo* (*Friend of the People*). The advanced Liberals had founded the *Estrella Polar* (*Polar Star*) and *El Fantasma* (*The Phantom*) in 1824. The journals of this period were shortlived and were mostly political publications.

Santa Anna Period. — Although Antonio López de Santa Anna was as much opposed to the freedom of the press as his predecessors had been, a great many publications made their appearance under his government. In 1841 *El Siglo XIX* (*The 19th Century*), a most influential Liberal newspaper, made its appearance in Mexico City. Eleven other publications of a political or professional nature were also published during this period. The *El Monitor Constitucional* (*The Constitutional Monitor*), a publication of great influence and longevity, was first published in 1842. Its name was changed in 1844 to *El Monitor Republicano* (*The Republican Monitor*).

During the occupation by United States troops (1847–1848) two newspapers favoring them were published in the State of Veracruz. These were *El Boletín de Veracruz* (*The Veracruz Bulletin*) and the Xalapa (Jalapa) *Estrella Americana* (*American Star*). Opposed to the occupation were the Mexico City *El Eco del Comercio* (*The Echo of Commerce*) and *La Patria* (*The Nation*). After the occupation was ended, Santa Anna published *La Palanca* (*The Lever*), opposed to President Mariano Arista; and another newspaper, *El Universal* (*The Universal*), favoring a monarchy with a European ruler, made its entrance onto the journalistic stage. This newspaper was destroyed by an enraged mob on Aug. 13, 1855. *El Monitor Republicano,* which had ceased publication, now reappeared, and following Santa Anna's fall from power (1855) the *Heraldo Liberal* (*Liberal Herald*) was born. The struggle between the Liberal republican press and the Conservative press now reached its highest peak.

French Occupation, Maximilian's Empire, and Reform Period.—The cleavage between the Liberal and Conservative parties was greatly accentuated during this period and was reflected in the press. The following publications favoring the monarchy were published during Maximilian's reign (1864–1867): *La Monarquía* (*The Monarchy*); *L'Estafette* (*The Courier,* published in French); *La Patria,* no relation to that mentioned above; *La Sociedad* (*The Society*); *El Cronista* (*The Chronicler*); *El Espíritu del Pueblo* (*The Spirit of the People*); *El Franco-Mexicano* (*The Franco-Mexican*); *La Constitución Social* (*The Social Constitution*); *La Raza de México* (*The Mexican Race*); and others. Opposed to the monarchy were: *La Orquesta* (*The Orchestra*); *El Hijo del Ahuizote* (*The Son of the Ahuizote*); *La Sombra* (*The Shadow*); *La Cucaracha* (*The Cockroach*); *El Espejuelo del Diablo* (*The Devil's Mirror*); *El Clamor Progresista* (*The Progressive Clamor*); *El Año Nuevo* (*The New Year*); *La Voz del Pueblo* (*The Voice of the People*); and *El Payaso* (*The Clown*). Marshal Achille Bazaine, commander of the French forces, prohibited opposition journals from publishing in 1863; however, *El Payaso* and *El Hijo del Ahuizote* reappeared and continued in business up to the regime of Porfirio Díaz.

The administration (1867–1872) of President Benito Juárez was notable in that complete freedom of the press existed. A great number of

periodicals were published during this period. His government was the subject of bitter attacks by the pro-Catholic press, namely *La Voz de México* (*The Voice of Mexico*) and *La Idea Católica* (*The Catholic Idea*), but in spite of this opposition they were permitted to continue functioning without interference from the government.

Porfirio Díaz Dictatorship.—The stability of the Díaz government (1876–1911) resulted in the creation of sound journals and journalistic principles. Many papers were opposed to the government, but there were also many which defended it. In 1896, Rafael Reyes Espindola (1860–1922) founded *El Imparcial* (*The Impartial*), the first Mexican daily to have a well-trained editorial and reportorial staff and the latest in printing presses. In 1906, with the growth of opposition to Díaz, *El Imparcial,* pro-Díaz, *El Popular,* slightly leftist, and *El País* (*The Country*), Catholic and pro-Díaz, vied for the public's favor.

Contemporary Journalism.—The end of the Porfirio Díaz dictatorship in 1911 marks the rise of modern Mexican journalism. Between the years 1910 and 1917 the most outstanding newspapers were: *El Antireeleccionista* (*The Anti-Reelectionist*), the most important of those defending the Constitutionalist revolution; *El Imparcial; El Debate* (*The Debate*), pro-Díaz; *El Nuevo México* (*The New Mexico*), anti-Díaz; *La Nueva Era* (*The New Era*), pro-Díaz; *El Mañana* (*Tomorrow*), anti-Madero; *La Tribuna* (*The Tribune*); and the anti-Díaz *El Mexicano* (*The Mexican*), *El Pueblo* (*The People*), and *El Universal.*

Excelsior was founded in 1917, as was *El Universal,* which papers were inspired by United States journalistic methods and editorial policies.

The approximate circulations of important Mexico City newspapers in 1953 were: *La Prensa* (*The Press,* tabloid) 119,300; *Excelsior,* 91,367; *El Universal,* 83,751; *Novedades* (*News*), 80,000; *Ultimas Noticias* (*Latest News;* noon and afternoon daily published by the *Excelsior*), 79,940; *El Universal Gráfico* (pictorial tabloid published by *El Universal*), 25,307; *El Nacional* (*The National,* government journal), 25,000; *El Popular* (official organ of the labor organization Confederación de Trabajadores Mexicanos), 12,000; and the sports daily *Esto* (*This*), 10,000.

There is an English-language daily, *The News* (circulation 10,000), and an English section in the *Excelsior.* The *Journal Française du Mexique* (3,000), is the only French daily of consequence.

There are countless weekly magazines published in Mexico City, of which the most important are: *Todo* (*All*), approximate circulation in 1953, 30,000; *Revista de Revistas* (*Review of Reviews*), 25,000; *Hoy* (*Today*), 20,000; *Mañana* (*Tomorrow*), 20,000; and *Tiempo* (*Time*), 20,000, which in format closely resembles the *Time* magazine of the United States. A great variety of bullfighting periodicals, such as *Redondel* (30,000) and *Claridades* (21,500), are published weekly, with another group of periodicals dedicated to all the sports practiced in Mexico. In the provinces a great number of publications are published daily or weekly, rivaling in number those published in Mexico City. Of these the largest daily papers are *El Norte* of Monterrey, *Diario de Yucatán* of Mérida, and *El Informador* of Guadalajara. The García Valseca newspaper chain publishes seventeen out-of-town newspapers.

Statistical Data.—The number of readers per copy in 1950 was 21.7, which places Mexico considerably below the United States and Great Britain. However, among the Spanish-speaking countries, Mexico occupies first place in readers per copy. In 1936 (the last year for which figures are available) the number of readers per daily was 23.1 per copy; weekly publications, 28.4 per copy; and monthlies, 24.8 per copy.

The total number of publications in Mexico in May 1952 was 1,515, of which 136 were dailies; 321 weeklies; 651 monthlies; others, 407. They may be divided by subject matter as follows: 841 general information (including 32 whose appearance was so irregular that they are not included in the foregoing); 208 religious; 184 technical scientific; 69 cultural; 44 literary; 43 political; 38 for children; 34 sports; 24 labor; and 62 miscellaneous. These figures show the progress that has been made in Mexico, and the evolutionary step taken from political journalism to informative journalism, a phenomenon which reflects the stability and coming of age of a country.

10. GOVERNMENT. Government is the organism for the administration and realization of the aims of the state. In the case of the Aztecs, their government, as it was encountered by the Spaniards, had undergone considerable evolution since the first tribe settled on the site of Mexico City, then an island in Lake Texcoco (or Tetzcoco). In the first third of the 16th century the supreme political, judicial, administrative, and military authority was vested in the *tlacatecuhtli,* or *hueytlatoani,* who was elected by a council of four electors from the nobility. After the election of the first *hueytlatoani,* named Acamapichtli, however, this office was always bestowed upon his descendants. It thus appears that the Aztecs were governed by a single dynasty, the last of whom was Montezuma II.

To describe the colonial government would be to repeat the history of the viceroyalty (see the section *Spanish Conquest and Colony*).

During the Spanish domination Mexico was ruled by laws emanating from the Spanish crown. After its initial declaration of independence in 1810, New Spain was granted some concessions in the Spanish Constitution of 1812, which went into effect Sept. 28, 1812, but was suspended on December 5 following, and due to events in Spain was not again put into effect until 1820, only a year before Mexico achieved its independence.

Meanwhile, the Constitution of Apatzingán, abolishing slavery, had been promulgated by the Mexican insurgents on Oct. 22, 1814. Although it was never put into effect, this constitution is historically interesting, since it clearly states the concepts of the liberator, José María Morelos y Pavón, and his inner circle of followers, who established the organization of the country on a self-governing basis. It provided for universal suf-

frage, a congress which was to appoint a three-man executive, and a supreme court.

The independence of Mexico was achieved in 1821. Nevertheless, the new government was dominated by the landed gentry and the clergy for many years until the thorough-going reforms of the Constitution of 1857 were achieved.

On Feb. 24, 1821, the Plan of Iguala, considered the first Mexican constitution, was signed by Vicente Guerrero and Agustín de Iturbide, and the country was organized as a constitutional monarchy. After the overthrow of Iturbide's short-lived empire, a constitutional act of Jan. 31, 1824 reflecting various Anglo-American influences of the 18th century, was decreed and went into effect on October 4 of the same year, establishing a federal republic.

A movement toward a more centralized government took place on April 22, 1833, when a statement of basic principles was issued. These were the basis of the so-called Siete Leyes Constitucionales (Seven Constitutional Laws) of Dec. 29, 1836. This code was quite explicit with regard to individual rights, although it did not recognize freedom of religion, and organized a centralized republic, changing the states into departments. The Siete Leyes were later rejected by Antonio López de Santa Anna in his decree of June 12, 1843 (the so-called Bases Orgánicas), by which he virtually re-established the centralist organization of 1821. The federalist Constitution of 1824 was re-established, Aug. 22, 1846, to promote unity during the war with the United States.

The Plan of Ayutla, which led to the overthrow of Santa Anna in 1855, was proclaimed on March 10, 1854, and later modified at Acapulco. This federalist constitution contained a declaration of the rights of man and certain advanced ideas.

The Reform, or Constitution of 1857 (promulgated February 5), re-established the Constitution of 1824, but contained the germ of a truly liberal law creating the right of judicial protection (see *Legislation and Jurisprudence*).

In the Revolution of 1910, a violent uprising finally terminated the dictatorship of Gen. Porfirio Díaz, under which a wealthy minority oppressed the miserably poor masses. Venustiano Carranza convoked a constituent congress in Querétaro, which approved a new political constitution on Jan. 31, 1917. It was promulgated Feb. 5, 1917.

Constitution of 1917.—The Mexican government was established in the following forms:

(1) *Constitutional*, because it is governed by the Constitution of 1917, which is the fundamental charter and basis of its politico-administrative organization. This constitution establishes the other characteristics of the government.

(2) *Republican*, since the national sovereignty rests with the people, from whom are derived all public powers; they having at all times the right to reform or modify the form of their government.

(3) *Representative*, because the people, by means of organisms created by the constitution, exercise their control over the government.

(4) *Democratic*, for these powers are exercised by each and every Mexican citizen.

(5) *Federal*, for the nation is composed of states, internally free and sovereign political entities joined together by a federal pact, or constitution, which determines the relationship and powers of the federal and local governments.

(6) *Presidential*, because the president freely appoints his aides and cabinet ministers, and because of the independence which the latter enjoy in relation to the legislative chambers.

The government is exercised by federal and local authorities. The federal government is divided for its functions into legislative, executive, and judicial branches.

Legislative Branch.—This is divided into two houses. The Cámara de Diputados (House of Representatives) is composed of national constituent representatives (*diputados*), directly elected for three years, one for each 150,000 inhabitants or fraction over 75,000. Each representative has an elected alternate who takes his place in case of absence or death. In no case may there be less than two representatives for each state, nor less than one per territory. The election of July 6, 1952 named 160 representatives. The other house, the Cámara de Senadores (Senate), is composed of two members (*senadores*) from each state and two from the Federal District, also directly elected and replaced in their totality every six years. An alternate is also elected for each senator. Territories are not represented in the Senate.

Together the two houses compose the Congress of the Union. Their resolutions are called laws, if issued by the Congress, or decrees, if issued by the president when invested by the Congress with extraordinary powers. Their ordinary period of sessions is from September 1 to December 31, at the latest. During their recess there is a permanent congressional commission composed of 29 members (15 representatives and 14 senators).

Executive Branch.—The executive power is vested in a single individual, the president, who is selected by direct election for a term of six years beginning on December 1, and is not eligible for re-election. He must be Mexican by birth, the son of Mexicans by birth, at least 35 years old, and may not be a clergyman, nor have been in active military service for at least six months before election.

There is no vice president. If a vacancy occurs during the first three years of a presidential term, new elections are held; if it occurs during the last three years, Congress may elect a successor for the remainder of the term.

The Ley de Secretarías y Departamentos de Estado enumerates and distributes the administrative matters entrusted to each branch of the executive power. This law came into effect on Dec. 7, 1946; it was reformed on May 1, 1947. The following are the cabinet posts:

(1) Secretaries (heads of the *secretarías*) of: Gobernación (Interior); Relaciones Exteriores (Foreign Relations); Hacienda y Crédito Público (Treasury); Defensa Nacional (National Defense); Marina Nacional (Navy); Agricultura y Ganadería (Agriculture and Livestock); Comunicaciones y Obras Públicas (Communications and Public Works); Economía Nacional (National Economy); Educación Pública (Public Education); Salubridad y Asistencia (Health and Welfare); Trabajo y Previsión Social (Labor and Social Welfare); Recursos Hidráulicos (Hydraulic Resources); and Bienes Nacionales e Inspección Administrativa (National Properties and Administrative Inspection).

(2) Department chiefs (heads of the following *departamentos*): Agrario (Agrarian); Distrito Federal (Federal District); and Industria Militar (Military Industry).

(3) Presidential cabinet assistants: attorney general of the republic; district attorney of the Federal District and territories; and the governors of the territories.

Judicial Branch.—The judicial power is vested in the Supreme Court of the Nation, circuit courts, district courts, and the federal public minister, who is appointed by and subordinate to the attorney general of the republic. See also the section *Legislation and Jurisprudence*.

State and Territorial Governments.—The basic unit of state government is the free *municipio* (municipality) administered by its municipal council (*ayuntamiento*). The president of the *municipio* and the members of the *ayuntamiento* are directly elected by popular vote. There is no intermediate authority between the *municipios* and the state governments, consisting of a governor and a Cámara de Diputados, both directly elected by popular vote. The governors' terms are limited to six years by federal law, and neither they, nor the members of the legislatures, nor the officials of the *municipios* may be immediately re-elected, without an intervening term. The state officials are appointed by the governors.

The *municipio* is also the basis of government in the territories. Governors of territories are named by the president of the republic, and they name the other officials. There are no territorial legislatures.

CARLOS R. BERZUNZA,
Colonel, Mexican Army; Professor of Geography, Universidad Nacional de México, Escuela Superior de Guerra, and Mexico City College.

11. POLITICAL PARTIES. The political struggles of Mexico after independence was achieved in 1821 took place between two ill-defined groups loosely labeled Conservatives and Liberals. The Conservatives were the party of the professional soldiers, the church, and the large landowners—in other words, the group which had inherited the economic and political power of the colonial period. The Liberals were the party of the middle class, the merchants, the nascent industrialists, and toward the end of the century, the industrial workers. The peasant group was largely controlled by the church and therefore cannot be considered as belonging to the Liberal group.

With minor interruptions, the Conservatives ruled the country from independence until the overthrow of Antonio López de Santa Anna by the Liberals in 1855. The Liberals then embarked on a program of reform which culminated in the Reform Laws (Leyes de la Reforma) of 1859–1860, decreed by Benito Juárez, which destroyed the economic power of the church by breaking up its extensive land holdings. The Conservatives, furthermore, were compromised in the unsuccessful scheme of Napoleon III to set Maximilian on the throne of Mexico. The long dictatorship (1884–1911) of Porfirio Díaz was thus born under the auspices of a Liberal victory.

The 20th Century.—Peace reigned throughout Mexico under Díaz. This was a period of material progress, railway construction, and industrial growth, but it weighed heavily on the peasants and workers. The political, military, and peasant rebellions, which appeared during the period, continued through the Revolution of 1910 up to the revolt of Gen. Saturnino Cedillo in 1938 during the presidency of Lázaro Cárdenas.

The Díaz period saw the emergence of new political parties, based on opposition to or support of the regime. San Luis Potosí was the birthplace (in 1901) of the anti-Díaz Club Liberal (Liberal Club), while in Mexico City the Asociación Liberal Reformista (Liberal Reformist Association) made its appearance. In 1908 both the pro-Díaz Club Reeleccionista (Re-electionist Club) and the group known as the *Científicos* ("Scientists") were formed, with definite despotic tendencies; in the same year the Partido Liberal de la Oposición (Liberal Opposition Party) emerged, and supported Francisco Madero against Díaz in the elections of 1910. Although Díaz was declared elected, the Partido Constitucional Progresista (Constitutional Progressive Party), also opposed to the re-election of Díaz, which would have meant a continuation of the dictatorship, carried Madero to power, with the aid of revolts by Pascual Orozco and Francisco Villa in the north in 1910, and by Emiliano Zapata in the south in 1911. Both rebellions, however, were peasant uprisings and did not accept revolutionary guidance from the cities.

Party labels had little meaning in the chaotic period which followed. Madero was assassinated by Victoriano Huerta, who assumed the presidency, 1913–1914. Venustiano Carranza drove Huerta from office, his regime lasting until 1920 when he was overthrown, and elections were held. Gen. Alvaro Obregón was elected president with the support of the Partido Laborista Mexicano (Mexican Labor Party), founded by the labor leader Luis Morones. It is interesting to note that the Partido Comunista de México (Communist Party of Mexico) was founded in 1922.

In 1924 Plutarco Elías Calles was elected president. In 1929 he founded the Partido Nacional Revolucionario (or PNR; National Revolutionary Party) as the official government party. The PNR has continued in existence, under various names, up to the present period. This political organization is a conglomeration of individual adherents, groups of varying political interests, and labor unions—all interested in maintaining the party in power. The army, which until 1914 had been a support of the conservatives, has become the supporter of constitutional rights and guardian of the conquests of the revolution.

During President Calles' term the Ley de Cultos was passed. This law was a definite blow at the church, and gave rise to the *Cristero* (Christist) revolt which began in 1927 and lasted up to President Portes Gil's regime in 1929. Gen. Lázaro Cárdenas, who gained wide popularity with the peasants and received the political support of the labor union Confederación de Trabajadores Mexicanos, in 1938 changed the name of the PNR to Partido de la Revolución Mexicana (PRM; Party of the Mexican Revolution), which launched as its candidate for the presidency in 1940 Gen. Manuel Ávila Camacho, who defeated Gen. Juan Andreu Almazan. General Almazan's Partido Revolucionario de Unificación Nacional (National Revolutionary Unification Party) was backed by groups similar to those which comprised the PRM.

President Ávila Camacho in 1946 changed the name of the official party to Partido Revolucionario Institucional (PRI; Revolutionary Institutional Party) which presented Miguel Alemán as its candidate for the presidency in the elections of that year. Alemán, the first civilian president after a long series of revolutionary generals, defeated Ezequiel Padilla by a vote announced as 1,800,829 to 431,487. Padilla was supported by the Partido Democrático Mexicano (Mexican Democratic Party), which was formed by dissident right-wing elements of the PRI.

The following candidates, with their respective parties and the number of votes they were officially announced as having received, participated in the elections of 1952: the victor, Adolfo Ruiz Cortines (2,713,419 votes), candidate of the PRI; Miguel Enríquez Guzmán (579,745 votes), candidate of the Federación de Partidos del Pueblo (Federation of People's Parties), a left-of-center group formed in 1952; Efraín González Luna (285,555 votes), candidate of the rightist Partido de Acción Nacional (National Action Party), founded in 1939, who was also supported by the Movimiento Sinarquista (Synarchist Movement), an adjunct of the *Cristero* movement, in the central and western states, and Vicente Lombardo Toledano (72,482 votes), candidate of the Partido Popular (Popular Party), founded in 1947, an appendage of the Communist Party.

Consult Sierra, Justo, *Evolución política del pueblo mexicano* (Mexico City 1940); also the declarations of various parties—Partido Nacional Revolucionario, *Constitución* (Mexico City 1934); Partido de la Revolución Mexicana, *Declaración de principios, programa y estatutos* (Mexico City 1938); Partido de Acción Nacional, *Declaración de principios* (Mexico City 1940); Partido Popular, *Razón histórica, principios, programa y estatutos* (Mexico City 1948); Partido Revolucionario Institucional, *Declaración de principios, programa y estatutos* (Mexico City 1950).

12. LEGISLATION AND JURISPRUDENCE. Although Mexico had every intention of modifying its constitutional law upon achieving its independence in 1821, a large part of Spanish law, which had been in force during the colonial period, was in fact preserved for many years. It had been variously codified and was used throughout the Spanish Empire and in the laws of the Indies, applicable to New Spain (Mexico) and other colonies. Therefore, Mexico belongs by legal tradition to the system of civil law, not of common law.

CONSTITUTIONAL AND ADMINISTRATIVE LAW

The first documents of Mexican public law were three documents of 1821, the Plan of Iguala (February 24), signed by Agustín de Iturbide and Vicente Guerrero, the Convention (or Treaty) of Córdoba (August 24) signed by Iturbide and Viceroy Juan O'Donojú, but not ratified by Spain, and the Act of Independence (September 28) signed by the governing junta, which tended to organize the new state as a monarchy; and, after the fall of the ephemeral empire of Iturbide, the liberator of Mexico, the Constitution of 1824. The constitution, which had been inspired mainly by the United States model and showed some influence of the Spanish Constitution of 1812, founded a democratic, representative, federal republic. This gave rise to a long-standing conflict between monarchists and centralists, those who favored a unitarian, not federal, government, on one side, and republicans and federalists on the other.

Following the trends of this struggle, the Siete Leyes Constitucionales (Seven Constitutional Laws) of 1836 and the Bases Orgánicas (Organic Bases) of 1843, both of which were constitutional changes, marked a return to republican centralization, and the decision of the Junta de Notables (Assembly of Notables) of 1863, a return to monarchic centralization under Maximilian of Austria. On the other hand the Acta de Reformas (Reform Act, amendments to the Constitution of 1824) drawn up in 1847, and the Constitution of 1857 insisted on a federal republic. This prevailed in the end, after the execution of the Emperor Maximilian in 1867.

Constitution of 1917.—The Revolution of 1910, which put an end to the regime of Gen. Porfirio Díaz, led to the proclamation of the Constitution of 1917. This turned out to be a revision of the one of 1857, and curbed the latter's excessive individualism, having very definite social tendencies, especially as regards certain public rights (such as freedom of commerce), the right to own land, and industrial relations. This constitution, which is still in force, although it has undergone various reforms, upheld a republican government which is democratic, representative, and federal, with a threefold division of power (executive, judicial, and legislative), and a presidential system. The federal authority has no power other than that granted by the constitution, since all other power is understood to be the prerogative of the member states of the federation. Nevertheless, it sets forth the principles to be observed by the various state constitutions in the organization of their governments, which must be democratic, representative, with a division of power, and have as the basis of political and administrative division the free *municipio* (municipality).

The constitution includes a chapter declaring fundamental public rights (limitations to the activities of public power), in which are named various individual guarantees. It is of a rigid type: the approval of two thirds of the members of both houses of the federal Congress, as well as of a majority of the legislative councils of the states of the union, is needed for any change in its provisions.

Legislature and Executive.—The Congress of the Union, made up of two chambers (Representatives and Senators), whose members are elected by popular vote, is vested with the legislative power. Apart from having the powers usually vested in a federal legislative body, it may also legislate on such matters as education, commerce, labor, mining, and on everything concerned with the territories and the Federal District, which is the residence of federal power and includes Mexico City. The president of the republic, who is elected by direct universal suffrage, is the head of the executive administration; he appoints and discharges the members of his cabinet, and he alone can issue directives for the enactment of and compliance with the law. (See also the section *Government.*)

Judiciary.—The federal judicial power is vested in the district judges (*jueces de distrito*), circuit courts (*tribunales de circuito*), and the Suprema Corte de Justicia de la Nación (Supreme Court). Their principal function is to watch over adherence to the constitution through the traditional *juicio de amparo* (judgment of protection), the most valuable and useful creation of Mexican law, the object of which is to repeal, on the petition of the interested party and only in so far as concerns the individual in his particular case, the ruling of any authority, executive, legislative, or judicial, state or federal, which may be against the constitution because of a violation of fundamental public rights guaranteed by the constitution, or because a federal ruling encroaches on the prerogatives of the states, or a state ruling encroaches on federal prerogatives. Any precedents set in five rulings of the Supreme Court in five similar cases are considered binding on the courts of the whole republic, except for the Supreme Court itself, which may alter later decisions, explaining whatever reasons it may have for such action.

Social Provisions.—Constitutional provisions relating to real property, trade, and industrial relations have been the source of numerous laws supplementing the principles of the constitution, such as the Ley sobre Monopolios (Monopoly Law) of 1931, Ley Federal del Trabajo (Federal Labor Law) of 1933, Código Agrario (Agrarian Code) of 1934, Ley del Seguro Social (Social Security Law) of 1943, and Ley de Facultades del Ejecutivo en Materia Económica (Law of the Powers of the Executive in Economic Matters) of 1950. The inclusion of these provisions in the constitution is explained by the desire of the constituent power that came from the revolution to make them prevail over changes of government.

Private property is guaranteed, and may be expropriated only by reason of public utility and with indemnity. But the state may impose on property such limits and regulations as are compatible with the public interest, and it may control the exploitation of those natural resources (such as minerals) susceptible of appropriation, in order to achieve a fair distribution of public wealth and its conservation. To this end, and in

order to solve the agrarian problem, the state may order large estates to be broken up, may foster the development of small agrarian properties, and may create new centers of agricultural population. Agrarian legislation is directed mainly to restoring to villages the communal water and land of which they were deprived in the past, and to providing them for communities that do not already possess them, taking them from neighboring property, but without harming the small units already in existence. Such land is subject to special provisions which aim at full private property. Apart from this, the nation is the sole owner of all mineral deposits and, except for petroleum, may grant the rights of exploitation to private persons. Petroleum is exploited exclusively by a state enterprise, Petróleos Mexicanos, an autonomous organization commonly known as Pemex.

As regards commerce, monopolies are forbidden, as well as exclusive control of essential goods, anything that may interfere with free competition in manufacturing or commerce, any action aimed at raising prices, and generally anything intended to give exclusive or undue advantage to one or several persons, to the detriment of the general public or of a particular social class. In the exercise of this principle the law allows the setting of ceiling prices for goods considered as essential, compulsory sales, and even in some cases the control of sources of production. At the same time, official organizations have been set up to compete in inland and international trade. These enjoy special privileges and franchises not granted private tradesmen.

As regards labor, workers are protected with respect to working hours, place of work, minimum wages, holidays, and unjustified dismissal, and are provided with social security against sickness of the worker or his family, invalidism, unemployment, old age, and with death benefits. These are brought about through individual, collective, or industrial contracts, which may never be lower than the minimum advantages which the law grants labor. Minors and women workers are also protected, and the right to strike or stop work for causes specified by law is granted. There are special tribunals to try labor conflicts, and their decisions are binding. See also the section *Economic, Industrial, Agricultural, and Financial Factors* (Modern Economic Policy).

CIVIL LAW

Until 1870 Mexican civil law was essentially the same as Spanish civil law, which was in force when independence was declared (1821). The Código Civil para el Distrito y Territorios Federales (Civil Code for the Federal District and Territories) was published in 1870, and this was soon replaced by another in 1884, which was in turn replaced by that in force, which dates back to 1932. The states have always adopted for their own use, with slight variations, the Civil Code for the Federal District. This code belongs to the group known as the Napoleonic codes, although it has been influenced by Spanish and Argentine civil legislation, and by the Swiss Code of Obligation. It controls family relations, succession, property, possessions, *derechos reales* (such as mortgages and easements), obligations, and contracts. Together with the recognition of the right to private property and the autonomy of will in contracts, a marked tendency toward the protection of social interests can be observed, getting away from the individualism of the code of 1884.

Commercial Codes.—Spanish law concerning trading matters was also accepted in its greater part until the Código de Comercio (Code of Commerce), applicable throughout the republic, was written in 1884. A new Code of Commerce was published in 1889. Both were along the lines of codes of the Latin countries of Europe, that is to say, Spain, France, Italy, and Portugal. The Code of 1889, however, is now valid only in certain fields, such as general trading operations, maritime commerce, and mercantile lawsuits, since, while awaiting the issuance of a new code, several laws have been passed which replace some of its chapters. The most important of these laws are the laws on: Títulos y Operaciones de Crédito (Securities and Credit Transactions) of 1932; Sociedades Mercantiles (Corporations) of 1934; Contrato de Seguro (Insurance Contracts) of 1935; Instituciones de Seguro (Insurance Concerns) of 1935; two measures relating to national financial institutions, Nacional Financiera (1940) and Banco de México (1941); Instituciones de Crédito y Organizaciones Auxiliares (Banking Institutions and Auxiliary Organizations) of 1941; Quiebras y Suspensión de Pagos (Bankruptcy and Suspension of Payments) of 1943; (and Instituciones de Fianzas (Bonding Companies) of 1950. It cannot be said that this new mercantile legislation follows a definite school, but Italian influence is predominant.

Penal Codes.—Excepting occasional decrees mainly of a political character, Spanish penal law continued to be applied in Mexico until the first Código Penal para el Distrito y Territorios Federales (Penal Code for the Federal District and Territories) was published in 1871. It followed the theories of the classical school and, as regards procedure, adhered to the fundamental rights of the defendant, clearly set out in the declaration of rights of the Constitution of 1857. This code remained in force until 1929, when it was replaced by the Código Penal and the Código de Procedimientos Penales (Code of Penal Procedure), which followed the most modern theories of the time. As these were found difficult to execute in the Mexican environment, they were in turn abrogated and replaced in 1931 by codes having the same names. The codes of 1931, also based on new ideas concerning penal matters, but of an eclectic nature, are more practical and have survived with practically no change. The states have largely adopted the penal legislation of the Federal District.

Summing up, it can be said that Mexico enjoys legislation that is modern in every branch, but is relatively unsettled because of the special political, social, and economic conditions of a country which is in the process of development and which has not yet worked out a system that may be called fully its own, fitting its particular idiosyncrasy.

13. NATIONAL DEFENSE. The armed forces of Mexico, as well as the whole country, have undergone a radical evolution, in accordance with advances throughout the world after World War II. The Secretaría de la Defensa Nacional (Department of National Defense) and the Secretaría de la Marina Nacional (Department of the Navy) were created on Dec. 1, 1940. These agencies had previously been joined together, under the title of the Secretaría de Guerra y Marina (Department of War and Navy).

Navy.—The Department of the Navy includes not only the fleet but also the merchant marine, and the bureaus of Obras Marítimas (Maritime Works), Dragado (Dredging), and Faros (Lighthouses) which previously belonged to the Secretaría de Comunicaciones y Obras Públicas (Department of Communications and Public Works), as well as the Departamento de Pesca (Bureau of Fishing), which had formed part of the autonomous Departamento de Caza y Pesca (Department of Hunting and Fishing). Thus, everything relating to the sea has been brought under the control of one department of the government.

The navy constructs its own lighthouses. On July 24, 1951, the port works of Mazatlán were completed, permitting the entry of ships drawing 24 feet of water. A dry dock functions at Salina Cruz, Oaxaca, for ships of 20,000 tons displacement, and another for 10,000-ton ships is in service at San Juan de Ulúa, in the port of Veracruz.

There are eight naval zone headquarters. On the Gulf of Mexico are the First, at Tampico; Third, at Veracruz; Fifth, at Carmen; and Seventh, at Mujeres Island. On the Pacific are the Second, at Margarita Island; Fourth, at Guaymas; Sixth, at Manzanillo; and Eighth, at Acapulco.

The naval academy, Heróica Escuela Naval Militar, formerly in the city of Veracruz, is at Antón Lizardo, Veracruz, in buildings completed in 1952. These are also the site of the Naval War College. The instruction imparted at the naval academy is considered among the best in the world in its field. There are also a naval aviation school at Veracruz and a school for sailors at Mazatlán. For the merchant marine, the Fernando Siliceo Nautical School at Veracruz is provided by the Department of the Navy.

The naval units are: 4 frigates, 3 gunboat-transports, 1 transport, 21 coast patrol craft, 4 auxiliary coast patrol craft, and 2 auxiliary ships. There is one marine battalion, and marine detachments, in each naval zone. The navy has about 8,000 men.

Army.—The army and its air force have achieved a notable progress in the years since 1940. The army takes considerable pride in its origins during the Revolution of 1910. By modern standards, its training and discipline place it among the best in Latin America. New officers for the army are procured from the graduates of the military academy, Heróico Colegio Militar, at Popotla, Federal District. There are also the following service schools: engineer, medical, signal, cavalry, noncommissioned officers, male nurses, nurses, and the Escuela Superior de Guerra (War College) in Mexico City; the latter being the highest level of studies in the army.

The regular army units are: 1 infantry division, 1 mechanized brigade, 1 mechanized cavalry regiment, 1 mixed brigade of presidential guards, 51 infantry battalions, 20 cavalry regiments, 2 artillery regiments, 3 independent artillery companies, 1 coast artillery battery, 2 battalions of combat engineers, 1 radar observation company, 1 signal battalion, and 1 quartermaster battalion. The corps of engineers is divided territorially into 8 engineer districts. The army and air force number about 60,000 men, exclusive of those called to the colors under the national military training program.

There is a central military hospital, modern in every respect, and an isolation hospital, both located in the capital, and six other military hospitals distributed throughout the republic. Mexican military surgeons enjoy great professional prestige.

Air Force.—This arm is part of the army, but has its own tradition—not only because the 201st Fighter Squadron fought on the Pacific front in World War II with the forces of the United States and other Allied nations, but also because Mexican pilots were the first to drop aerial bombs on warships, in 1913 during the revolution. It is composed of: 4 groups, 1 training group, 10 separate squadrons, and 1 battalion of paratroopers. Schools operated are the military flying school at Guadalajara; and the meteorology school, aviation mechanics school, and the parachutist school company at Mexico City.

National Military Service.—On Aug. 20, 1940 universal military training was commenced, obligating all 18-year-old youths to receive one year of basic training in the army. The draftees are organized under reserve officers into 43 infantry divisions, each of 3 regiments, plus 8 nondivisional regiments, all distributed according to population throughout the nation.

Military Territorial Divisions.—By a presidential decree of Feb. 20, 1952, the national territory was reorganized and divided into nine military regions (later one more was added), each commanded by a lieutenant general. Thus the 32 military zones, previously the base of territorial division, were subordinated to the respective regional headquarters, located as follows: the First, at Mexico City; Second, at Veracruz; Third, at Mérida, Yucatán; Fourth, at Ixtepec, Oaxaca; Fifth, at Guadalajara; Sixth, at Tijuana, Lower California; Seventh, at Hermosillo, Sonora; Eighth, at Torreón, Coahuila; Ninth, at Monterrey; and Tenth, at Irapuato, Guanajuato.

Military Industry.—On May 1, 1947 the Law of Secretariats and Departments of State was revised, creating the Departamento de la Industria Militar. This cabinet department is charged

with the operation of the munitions and arms factories which supply the national armed forces.

CARLOS R. BERZUNZA,
Colonel, Mexican Army; Professor of Geography, Universidad Nacional de México, Escuela Superior de Guerra, and Mexico City College.

14. EDUCATION. Pre-Hispanic.—When the Spaniards led by Hernán Cortés conquered Mexico, they encountered among the natives a fairly well-organized system of education. The education of the Maya and Aztec populations may serve as typical examples, although they are not the only Indian educational systems that might be mentioned.

Mayan education, which like science, was entrusted to their priests, was the medium through which religion and scientific learning were transferred to new generations. It is known that these learned men achieved a notable exactitude in astronomy and mathematics, and that their literary, architectural, and artistic achievements in general were of a high order. None of this could have been accomplished without an organized and efficient educational system.

Among the Aztecs, infant education was under the care of the parents, who were charged with responsibility for the physical development of their children, in conformance with a plan which indicated even the quantity of food that should be given to children and the exercises and tasks that gradually were to be entrusted to them.

The education of the Aztec people was imparted in three types of schools: the *calmecac,* the *telpochcalli,* and the *cuicalco.* The *calmecac,* joined to the great temple of the Aztec capital, Tenochtitlan, was a school for the children of both sexes of noble families, priests, military chiefs, and merchants. The education given in the *calmecac* was oriented toward the formation of public officials of the state, the priesthood, and the upper hierarchies of the army. The youths studied there from the time they were 15 until they became 22. Young girls studied in accordance with their own program appropriate to the social function of their sex, and remained in the *calmecac* completely separated from the males and under the care of instructors. The studies in the *calmecac* embraced astronomy, cosmogony, reading of the calendars, arithmetic, singing, dancing, civil and penal procedures, and military instruction.

The *telpochcalli* was an academy of the popular type; there being one in each section of the city of Tenochtitlan. At the age of 15, the sons of farmers and artisans entered these schools, remaining in them until they were 22. The teaching was oriented toward the formation of good soldiers and army officers. It consisted, fundamentally, in a gradual series of severe physical exercises to keep the students healthy and to make them strong. Knowledge of use of arms and training for combat were also taught; the latter included practice in real battles under the direction of an experienced chieftain. The excellence acquired in these practices was rewarded by distinctions which gave the young man the right to use insignia and to hold military rank. These aided the man ultimately in his entry into the army.

The *cuicalco* was a kind of general school where all the other young people of both sexes were concentrated to learn songs, dances, and religious rites under the direction of priests and matrons.

In general, Aztec education exalted the warlike virtues, respect for parents and hierarchical superiors, the cultivation of a rigid morality, the formation of religious feeling, and love of country.

Colonial.—Once the Indian peoples had been subjugated, the conquerors showed an inexorable determination to destroy the cultural institutions of the conquered. This determination is explained as a means of preventing a political and social resurgence of the conquered peoples and as a method of imposing the Catholic religion, whose propagation had been the moral justification of the conquest. As the Mexican education was intimately connected with the old religion and as it was directed toward the formation of a haughty and aggressive spirit, it was logically the target of the intolerance of the dominators.

The various religious orders that were coming to the colony founded schools in the various cities and monopolized education during the entire colonial epoch.

The new education, established in the country during the three centuries in which it was called Nueva España (New Spain), had well-distinguished characteristics. The first objectives, as far as the education of the people in general was concerned, were those of instructing them for conversion to Catholicism and imposing on them feelings of subjection toward the new social hierarchy and of resignation with respect to their destiny.

Experiments in Indian Education.—In 1536 Fray Juan de Zumárraga (1468–1548), later to become the first bishop of Mexico, with the aid of the first viceroy, Antonio de Mendoza, founded the Imperial Colegio de Santa Cruz de Tlatelolco, just north of Mexico City, dedicated exclusively to the education of Indian children. In the beginning, this school imparted elementary and advanced studies; later it was limited merely to advanced education, and it finally became an elementary school.

The children were taught in their own language, Nahuatl, and their instruction was directed by such eminent men as Fray Bernardino de Sahagún (1499?–1590). The school proposed that the Indians instructed in it be converted into missionaries of the Catholic faith and given the responsibility of going out to convert their own peoples.

Santa Cruz de Tlatelolco had such amazing success that notable Indians imbued with the humanistic spirit left its lecture halls to become teachers of the Spaniards themselves, and eventually they opened their own way to positions as mayors and governors in the colony.

But while progressive and generous spirits existed in the colony, there were many intolerant and distrustful persons in leading posts. The latter became alarmed at the success of Santa Cruz de Tlatelolco and began a decided policy of hostility against the school, until in 1595, they were successful in reducing it to an elementary institution. Its brief existence was nevertheless sufficient to demonstrate graphically the great possibilities of the native population.

In 1540, Vasco de Quiroga (1470–1565), first bishop of Michoacán, founded the Colegio de San Nicolás Obispo, in Pátzcuaro, dedicated to the Indians. In this school also, the teachers spoke to the children in the language of their

fathers, Tarascan, because, as Bishop Quiroga said, this was the only bridge over which he could reach the brain and the heart of the Indians. The teaching of subjects was organized around practical activities. The children practiced agriculture for certain hours; in others, the apprenticeship of crafts. These crafts were those which the great educator felt would best take advantage of the native artisan tradition then extant, the available raw materials, the new experiences that his European culture had brought, and the great artistic aptitudes of his students.

The experiment of Vasco de Quiroga had such a powerful effect and left such a deep impression that, after four centuries, his deeds still live in the minds of his people. Nor have they forgotten the artistic crafts he taught; even today their work attracts the admiration of both Mexicans and foreigners.

University of Mexico.—In 1539, Fray Bartolomé de las Casas assumed the initiative for the creation of a university in Mexico City and took the plan to Emperor Charles V, who in 1551, ordered the foundation of the Real y Pontificia Universidad de México (Royal and Pontifical University of Mexico), granting it the same privileges that were enjoyed by the University of Salamanca, Spain, and a subsidy for its maintenance. It opened its doors in 1553, and the pope confirmed the foundation and privileges in 1555. Thus was born the greatest institution of higher learning in the country, now called, in full, the Universidad Nacional Autónoma de México (National Autonomous University of Mexico). The National University and the University of San Marcos in Lima, Peru, are thus the oldest universities in the Americas.

The 19th Century.—With the consummation of independence in 1821, and for many years thereafter, education underwent practically no alteration, but eventually criticism against a system of education that was monopolized by the clergy and that retained medieval methods of teaching brought on a vigorous change. José María Luis Mora (1794–1850) and Valentín Gómez Farías (1781–1858) were among the ideologists of the new movement.

Gómez Farías became president of the republic in 1833 and immediately initiated an educational reform. A commission, whose duty it was to study the condition in which the centers of education were maintained, in order to propose reforms, found that the University of Mexico was a "useless, unreformable, and pernicious institution."

Until the Liberal triumph in 1865, education was a field in which incidents in the conflict between Liberals and Conservatives were well reflected. The latter were the partisans of a regime of privilege and intolerance in behalf of the Catholic Church and of a social order similar to that of the colony. The Liberals, on the other hand, aspired to a regime of religous tolerance, to the separation of church and state, and to a democratic political organization within a federal system.

While schools supported by the church declined, the Lancasterian Company, which operated through private initiative and with a government subsidy, handled the most important field of study, primary education. The success of the Lancasterian schools, organized in conformity with the ideas of the English educator Joseph Lancaster (for which see LANCASTERIAN SCHOOLS), dominated this field from 1822 to 1890.

In 1865 the Liberals, led by Benito Juárez, triumphed definitively and initiated the reorganization of education. The University of Mexico, which had been closed three times (1833, 1857, and 1861) and reestablished each time, was finally closed in 1865, since it was considered a center of the reactionary mentality; its doors remaining shut until 1910.

Higher education was established in separate professional schools, with the Escuela Nacional Preparatoria (National Preparatory School) as a common basis. The latter school, founded in 1867, taught teaching methods and prepared persons for entry into the professional schools. Its organization, the work of Dr. Gabino Barreda (1818–1881), was founded on the positivistic philosophy of Auguste Comte. It gave special preference to the teaching of the sciences and eliminated all religious or dogmatic teaching; scientific, positive, and demonstrable truth being considered valid against all types of speculative science. The plan of studies followed the order of the Comtian law of the historical appearance of the sciences: mathematics, astronomy, physics, chemistry, biology, and sociology.

To end the influence of the clergy through the educational activities of the priests, normal schools were founded, and the professional teacher, with a specialized preparation, then appeared. From that time, normal schools prepared lay teachers with Liberal views and ideas. Those who directed this movement with notable competence were: Enrique C. Rébsamen (1857–1904), of Swiss origin; Enrique Laubscher, who in 1883 founded the first kindergarten in Mexico; and Carlos A. Carrillo (1855–1903). The educational method in vogue, called the intuitive method, consisted in putting the child in direct contact with things and nature instead of telling him about them. Justo Sierra (1848–1912), undersecretary of justice and public instruction under the regime of Gen. Porfirio Díaz, was the representative of the government in educational matters.

New Education.—By 1920 the revolution which had put an end to the Díaz dictatorship had consolidated its triumph, and in 1921 the Secretaría de Educación Pública y Bellas Artes (Department of Public Education and Fine Arts) was created. It was charged with the development of educational programs and served as an organ of the federal government.

The situation that the new regime immediately encountered may be summed up: (1) a great amount of popular ignorance, with an illiteracy rate of 66 per cent; and (2) a standardized pedagogic organization imported from urban Europe, without adaptation to the necessities and characteristics of Mexico, where a large group of the population is rural.

Government-sponsored education and the educational methods adopted were a reaction against this state of affairs. The government increased, in proportions without precedent, its budgets for education—in 1921 it was four times larger than in 1920 (when it was 2,218,165 pesos); in 1922 it was 13 times larger, and in 1923 it became 15 times larger than in the initial year.

Illiteracy.—To instruct the illiterate adult population, anti-illiteracy (*desanalfabetización*) campaigns were organized and night schools were created. As a result of these efforts, the

proportion of adult illiteracy has been steadily reduced—from 70 per cent in 1910, to 66 per cent in 1921; to 59 per cent in 1930; to 47.8 per cent in 1940, and to 36.68 per cent in 1950.

Rural Schools.—Special schools were created for the rural population, beginning with 85 in 1922. The rural school was defined in 1926 as a school in which it was proposed: (1) to better the conditions of life in the community by teaching better methods of work; (2) to teach less within classrooms and more outside in the community; and (3) to teach a practical program, the knowledge to be learned to be selected according to the necessities of communal life and to be acquired in the course of managed activities to satisfy rural needs. It is not merely a rudimentary education, but a special kind of education for country people, and includes all grades from the lowest to the highest. The aim was to create a secondary educational system, and later to add a higher education. The rural schools were very successful and grew rapidly from practically nothing. In 1949 there were already 18,840 spread throughout the country.

To prepare a teaching personnel adequate for the rural schools, regional normal schools were founded; however, these were unable to produce teachers in proportion to the number of schools that were being created, and many persons without previous preparation had to be accepted. To prepare the latter group, the Instituto Federal de Capacitación was created in 1945. Their needs are being met by means of a combination of courses by mail, and short, intensive periods of study in classes.

Cultural Missions.—The *misiones culturales* were created in 1923 with a view to reducing the differences in conditions of life between city and country. Various specialists, such as agronomists, hygienists, social workers, technicians, and others, under the direction of a normal school teacher, went to the more distant and undeveloped places, which they themselves chose. There they developed programs for the improvement of economic and social life in the community, working with the citizens. The latter, upon cooperating in the program for their own betterment, learned superior methods of work and life, whose value is lasting.

Indian Education.—Indian education is focused in a special manner, since at an early date the conviction was reached that the imposition of the Spanish language on the Indian population, which speaks a variety of tongues, is not an adequate way to educate the Indian, because it produces resistances, and stumbles upon other difficulties that neutralize the effort. On the other hand, it is much easier to impart useful, scientific, and technical knowledge in the mother tongue, achieving an immediate educational influence, while at the same time opening an accessible and interesting way to learn Spanish, and a sure way of integrating the rural Indian peoples into the national community. Complementing this educational program, periodicals are published in the native languages at experimental centers. These publications have had spectacular results.

Toward a Mexican Pedagogy.—In 1925, the Departamento de Psicopedagogía e Higiene (Department of Pedagogic Psychology and Hygiene) was created, which in 1939 was transformed into the Instituto Nacional de Psicopedagogía (National Institute of Pedagogic Psychology). The institute's mission is that of organizing scientific investigations into Mexican social and scholastic methods. It is proposed eventually to build up a pedagogy that answers to reality and is not merely an exotic importation. In the same spirit, the Instituto de Perfeccionamiento de Maestros de Enseñanza Secundaria (Teacher's Institute of Secondary Instruction), transformed later into the Escuela Normal Superior (Superior Normal School), was founded in 1937 for graduate teachers to improve their work.

Higher Education.—The disputes between radicals and conservatives that made the life of the university so unfortunate in the 19th century were resolved in 1929 by giving legal autonomy to the National University and a substantial subsidy from the government for its maintenance. The course of studies in the humanities and in the formation of the liberal professions of the traditional type has been left to the university. Under these conditions it prospers, and has also been converted into the leader of the network of other universities established in the principal cities of the country.

On the other hand, the aspiration toward a higher education that would place the more advanced scientific knowledge and technique at the service of the industrial development of the country, noted before in the Liberal ideologies of the 19th century, was made a reality with the establishment (1936) of the Instituto Politécnico Nacional (National Polytechnic Institute) in Mexico City during the administration of President Cárdenas. Built upon the same basis as the national institute, but with adaptations to local necessities and resources, local technological institutes exist in various states and others are being set up. Among the most noted of these educational centers are those at Monterrey and Guadalajara.

The education of technicians in the field of agriculture and cattle raising relies upon various agricultural schools of the middle grades, in whose courses more than 5,000 students are enrolled, and upon three schools of the upper levels. The latter are the Escuela Nacional de Agricultura, located in Chapingo, State of Mexico, and the agricultural schools of Narro, Coahuila, and Ciudad Juárez, Chihuahua. The first named dates from 1854; all the others are the work of the educational reforms which grew out of the revolution.

Educational Policies.—The development of the contemporary educational work which has been described does not follow a constant rhythm, either in intensity or in technical organizational efficiency. The economic vicissitudes of the government and the greater or lesser progressivism and interest of the political leaders in office have made the intensity and the effectiveness of the educational endeavor variable. The impulse given to education by presidents Obregón (1920–1924), Calles (1924–1928), and Cárdenas (1934–1940) should be mentioned, since during their administrations education received a generous attention, expressed in the large portions of the general government budgets designated for its use.

The first secretary of public education in the constructive era of the revolution was José Vasconcelos, from 1921–1924, but the credit for orienting and constructing the new Mexican education along definite lines goes to the group of professional teachers who constituted the staff of the Secretaría de Educación Pública during the more fruitful years. Distinguished teachers gathered around Professor Lauro Aguirre (1883–1928), who edited the magazine *Educación.* Among these was Professor Moisés Sáenz (1888–1941), who was

undersecretary of public education (1925–1930), in the administration of General Calles, which, in fact, implied responsibility for the technical direction of the programs. Lauro Aguirre was placed in charge of the preparation of new teachers in the reform of normal-school education, and Alfredo Uruchurtu (1884–1940) became the chief administrator of this program. José María Bonilla (1872–) and later Rafaél Ramírez (1885–) were in charge of organizing rural education. José Guadalupe Nájera (1889–) assumed the office of chief of the cultural missions. Other posts of similar importance were occupied by professors Manuel Barranco (1881–1945), José Arturo Pichardo (1863–1933), and Leopoldo Kiel (1876–1943). This is the team which, from the technical-pedagogical point of view, effected the most skillful, transcendental, and ample work of education in the history of Mexico.

In more recent years, with the start (1940) of the administration of President Ávila Camacho, the vigorous rhythm characteristic of the early years has yielded to a slow decline, as a consequence of the practical exclusion of professional teachers from the direction of educational endeavors. Their successors have not had a clear and deep vision of the meaning of the new educational institutions; thus they did not continue the development of those institutions with the same enthusiasm and ability. Their lack of deep concern for education is shown by the following data.

The financing of education took 6.78 per cent of the general expenses of the federal government in 1950. For this same work, 13.35 per cent of the general budget was applied in 1937, while in 1923 it was 15 per cent. This has necessarily affected the quality and the amplitude of the service. In 1950, for example, the proportion of the population of primary school age being adequately instructed was reduced to 44.6 per cent; contrasting with 54.7 per cent in 1938 and 71.8 per cent in 1939.

There are, nevertheless, reasons for thinking that this period of decline will be transitory and that Mexican education will recover the progressive momentum that was earlier achieved, and which distinguished the Mexican nation.

15. CHURCH AND STATE. Relations between church and state in Mexico have passed through a multitude of vicissitudes which have oscillated between complete harmony and open war. To understand the situation of those relations in modern times it is necessary to know the historic antecedents. For the purposes of this article, therefore, the study has been divided into six historical periods.

Indian Basis.—The tyrannical and primitive political forms which the Spaniards encountered in that part of the New World which today is the Mexican Republic were of a theocratic and warlike type, with diverse shadings among the different peoples. All of them were idolatrous, but particularly so were the most powerful, the Aztecs, who dominated the Central Plateau, and who practiced a barbaric worship based on human sacrifice and even cannibalism, in which the number of victims came to 100,000 annually. Although they had priests and warriors as different social castes, a real institutional distinction between political method and religious organization did not exist.

Discovery and Conquest.—The Catholic monarchs, Ferdinand and Isabella, and afterwards Charles V and Philip II, as also their successors, took an apostolic view of the discoveries and conquests that, beginning with Christopher Columbus, they made in the New World. Thus, with respect to the conquest, they considered the propagation of the Christian faith in the newly discovered lands as their primary duty.

Hernán Cortés and the other conquerors were nearly always accompanied by missionaries. They not only required of the Indians submission to the king of Spain; they also destroyed temples and idols in order to uproot the sanguinary religion of the Indians and asked them to adopt the Catholic faith. In other words, the Spanish state patronized the conversion of the Indians. It also prescribed wise laws for the incorporation of these Indians into Christian civilization. In spite of this, however, the conquerors and the delegates of the Spanish government committed many real abuses; at the same time, the cause of the natives was continually defended by the missionaries, such as Fray Toribio de Benavente (known as Motolinia), and by bishops like Juan de Zumárraga and Vasco de Quiroga.

In the work of evangelization undertaken in America, the Spanish crown received special privileges from the church, which allowed it to intervene in ecclesiastical discipline. Among these were the concession of tithes, the royal Indian patronage (*patronato real*), and the tribunal of the Inquisition. The tithes—or rather the proportion of the gross products of the fields and herds—that the inhabitants paid to the church for the support of its personnel, its worship, and its pious works were granted to Spain by Pope Alexander VI in 1501. In return the church imposed on the government the obligation of defraying these expenses. The rulers accepted the concession, but retained only two ninths of the collection, leaving the balance to the church.

The Bull *Universalis Ecclesiae* issued by Pope Julian II in 1508, and the wide interpretation that the Spanish monarchs gave to it, allowed them, among other things, the right to present candidates to fill the bishoprics and ecclesiastical offices, to issue royal licenses before churches, monasteries, and hospitals could be built, and to issue governmental permits before the bulls and other papal documents could be published and obeyed in the Indies. Numerous unjustified acts were committed by the kings and their officials in the government of the church in New Spain (Mexico) under the pretext of this royal patronage.

For its share, the government endeavored to prevent people who did not profess the Catholic faith from going to New Spain, with the end of maintaining the unity of the faith. Within this policy Philip II, by royal decree in 1569, established the Holy Office of the Inquisition in

New Spain, with the object of preserving the religious unity of the area, isolating heretics, and punishing their errors with the rigor demanded by the laws of the crown. Many have exaggerated the cruelty of the procedures and the penalties of the Inquisition, which in reality were ordinary for that period. From the solemn foundation of the tribunal until its suppression in 1820, only 36 persons were delivered by that tribunal to the secular arm for capital punishment by burning; this in 11 *autos de fé* from 1574 to 1715. After the latter year no death sentences were imposed.

Colony.—French influence and the organization of Freemasonry drove the Spanish government, in the last third of the 18th century and the beginning of the 19th, to a cooling of religious ardor and to a growing intervention in church affairs, which culminated in the Spanish Constitution of 1812 and in subsequent policy, all of which was reflected clearly in New Spain until that colony gained its independence in 1821. One of the most evident earlier manifestations of this change in religious policy was the dissolution and expulsion of the Jesuits from the Spanish dominions in 1767, during the reign of Charles III, and the occupation by government officials of the property belonging to that order, which was one of the most prosperous and active and was dedicated principally to teaching. Mention should also be made of government obstruction, in Spain and in the colony, to the extension of teaching and welfare work, which until then had been completely in the hands of the church and the religious orders. Some of the latter had to withdraw from New Spain or were deprived of their buildings by the government on the pretext of benefiting the national economy, and were fenced in with obstacles that impeded the discharge of their responsibilities.

Independence.—The people of New Spain and their leaders had remained eminently Catholic. It was very natural, therefore, that the Catholic religion should be the only one permitted and protected by the laws—in the constitutional project elaborated at Apatzingán under the direction of the insurgent José María Morelos in 1814 during the struggle for independence; in the Plan of Iguala, which served as a basis for the effective realization of independence in 1821, and was drawn up principally by Agustín de Iturbide; and even in the republican Constitution of 1824, written after the fall of Iturbide, who had been proclaimed emperor in the interim. The first independent governments sought to preserve privileges, such as the royal patronage which the kings of Spain had enjoyed in matters pertaining to religion, but were not successful.

The attack on the privileges of the Catholic Church was initiated—at first secretly, then in public form—principally because of the influence of Freemasonry established in Mexico. In 1833 the vice president of the republic, Valentín Gómez Farías, acting as president by permission of President Antonio López de Santa Anna, issued a series of expanding decrees to oppress the Catholic Church and to deprive it of its privileges. Among other measures, it dissolved the Royal and Pontifical University of Mexico (founded 1551) in the capital, secularized learning, and above all sought to interfere directly in parish affairs. A general clamor and various armed uprisings obliged President Santa Anna to intervene (1834) and to abandon some of these arrangements. Nevertheless, Gómez Farías, without success, had planned to nationalize the property of the church and to convert the priests into functionaries paid by the government.

Constitution of 1857 and Reform Laws.—There was a short period of harmony on the religious question until, triumphant in the Revolution of Ayutla (1854–1855), the ultraradical Liberals came to power. Under the presidency (1855–1857) of Ignacio Comonfort, plain civil war existed between the Conservatives, friends of the church, and the Liberals, their enemies. In 1855 Benito Juárez, as minister of justice and ecclesiastical matters, put forth a law which disentailed property held in *manos muertas* (mortmain), which obliged corporations, especially religious corporations, to sell their properties. A little later, in 1859, nationalization of all the property belonging to religious corporations was decreed. This, made under the pretext that the church, enormously rich, had abused its power by intrigues in politics, had as its only object the crushing of the church; as a result many politicians and foreigners became rich, buying up many of its lands at low prices. A great number of churches, schools, and hospitals were converted by the government to other uses.

Meanwhile, the Liberal Party in power had promulgated the Constitution of 1857. This established liberty for all religions and freedom of education, to stimulate the rivalry with Catholicism, deprived the priests of civil rights, disregarded the religious orders and gave the federal government the right to intervene in matters of religious procedure and in relations between the clergy and the people. With the civil war newly started again, the government led by Benito Juárez set forth the laws called the Reform Laws (1859–1860), which included the law nationalizing the property of the clergy and carried to an extreme the reprisals against the Catholic Church. After the downfall of the imperial adventure of Maximilian of Austria, whose regime (1861–1867) did not basically alter the religious situation, even though it tempered it notably, the Liberal Party remained definitively the victor, and in 1874 had the Reform Laws included in the constitution.

A long period of peace came in 1876, under the rule of Gen. Porfirio Díaz, the "strong man" who remained in power until 1911, when he was overthrown by the revolution led by Francisco Madero. During the regime of Díaz the laws against the church were maintained with vigor, but the church enjoyed, *de facto*, sufficient liberty, although certain policies of oppression were carried out, such as disregard of the legal status of ecclesiastical corporations, and prohibitions of public religious ceremonies outside the churches and of the use of special dress by priests and religious officials.

Constitution of 1917 and Its Application.—The Revolution of 1910 was not antireligious in origin, but it became so in a series of movements which culminated in the Constitution of 1917. The new constitution carried to the extreme the attacks on the church contained in the previous Constitution of 1857. Nevertheless, its provisions were not forcibly applied until 1926, the year in which President Plutarco Elías Calles let loose a true persecution against every kind of religious manifestation, commencing with limiting the number of priests to a ridiculously small figure, prohibiting foreign priests from performing the sacred offices in Mexico, as well as preventing all religious rites and religious instruction in private schools and even in homes; all under the threat of severe penalties, since all infractions of the laws on religious matters were considered criminal.

The clergy chose to suspend all ceremonies. A popular rebellion (the so-called *Cristero* movement) opposed the law for three years, but did not overthrow the government; because the latter was aided by foreign governments, the *Cristeros* could not obtain arms. Finally, in 1929, President Emilio Portes Gil reached an understanding with the church. Although the persecuting laws were not repealed, they were not applied in large part, or were executed with tolerance.

The church was again attacked in 1934 at the beginning of the administration of President Lázaro Cárdenas, principally in the matter of instruction. The Marxist tendency of the government led it to impose socialistic and antireligious education, and even to amend the constitution in that year.

From 1937, however, the *de facto* situation of the church and of religious matters in general has much improved. Relative liberty is enjoyed, since the antireligious laws that are in effect are in large part not applied, and the legislation relating to Marxist education was abolished in 1942–1946. As of 1952, benevolent, although unofficial, relations exist between church and state. From the constitutional and legal point of view, everyone may profess the religion of his choice in Mexico, but the public religious ceremonies must be held within precincts of the churches, in accordance with regulations that are dictated by and are under the vigilance of the authorities. Ecclesiastical corporations lack legal capacity and are not able to acquire property either directly or indirectly. All buildings dedicated to worship or religious education have been converted into national property. The priests do not have political rights, nor can they dedicate themselves to teaching or charity work. Both public and private religious education in the schools is prohibited.

16. PRE-HISPANIC ART. Mural Painting.—The great epoch of Indian mural painting, as far as both quantity and quality of output are concerned, coincides with the period which archaeologists label "Classic" (300 A.D. to 900 A.D.). At Teotihuacán, the great metropolis of central Mexico, a large number of murals have been discovered already, and it seems likely that more will come to light in the future. It is possible to distinguish an early style of painting at this site. This is found in a building which may be dated at 200 A.D. Its mural decoration is based on interlocking geometric designs with some symbolic religious motifs. The most recent style (dated roughly from 400 to 800 A.D.) is naturalistic, but not realistic. The content of the paintings is religious: they represent gods, priests, and sacred animals. Plants are also represented and some paintings even contain suggestions of landscapes. One of the most outstanding scenes represents the paradise of the water gods. Its liveliness of composition contrasts with the usual hieratic rigidity of Teotihuacán art.

The style of these paintings is characterized as follows: areas of flat colors delimited by contour lines; absence of modeling; no attempts to suggest space through the use of perspective or by other means. The technique used is partly fresco, partly tempera, on a base of calcium carbonate mixed with finely ground quartz sand. All the colors analyzed are mineral colors. Red was probably produced with hematite; yellow and orange with limonite and goethite; black possibly with magnesite; green with malachite or azurite. Reds were painted directly on the wet surface of the wall; greens were never painted in this fashion, but were applied as tempera over the white surface formed by the dry base. The application of transparent green on this white base results in a particularly brilliant green.

The murals of the big tombs of Monte Albán near Oaxaca (tombs Nos. 103, 104, and 105) belong to the same period. These paintings represent gods and goddesses, or priests dressed in cult ornaments. Here, as in Teotihuacán, the style is hieratic, but lines are drawn with greater freedom. The color scheme includes yellow, red, green, blue, white, gray, and black.

In 1946, ruins belonging to the Classic Maya civilization were discovered at Bonampak, in the Chiapas jungle. Among its buildings is one containing three rooms painted with different scenes. One of these shows richly dressed chiefs; servants dressing other men, perhaps chief priests, in ceremonial costumes; and musicians and dancers. Another gives an impressive picture of a battle and of victorious chiefs, surrounded by their guard, confronting a group of prisoners. The third painting represents another group of chiefs, musicians, and a big dance. Particularly significant is the fact that each of the paintings shows differences in rhythm, composition, and color scheme, according to its special content. The battle scene is characterized by the violent rhythm of broken lines and by somber colors. The scenes in which groups of chiefs appear show a composition of horizontal and vertical lines in equilibrium, and brilliant colors. The dancing scene shows an agitated rhythm of massed colors and undulating lines, which suggest movement. The technique employed in these paintings is also partly fresco, partly tempera. The color scheme includes yellow ocher, Indian red, orange red, burnt sienna, emerald green, dark green, turquoise blue, dark blue, white, and black. The Bonampak paintings are assigned to the 8th century A.D.

To a period after 1000 A.D. belong the paintings of mythological subjects which cover the altars of Tizatlán near Tlaxcala. The figures of gods are painted in the same style as the codices and the polychrome pottery of the Mixtec region of Oaxaca and the Valley of Puebla. This style, therefore, has received the name Mixtec-Puebla. Murals, painted in Mixtec-Puebla style, have also been found at Mitla, near Oaxaca. They represent mythological scenes, painted in red on a white background. An extension of this style toward the north has been found on the altar of Tamuin, in San Luis Potosí, near Valles. This painting, similarly red on white, shows a procession of gods and other figures.

In Yucatán, the murals of the Temple of the

Jaguars and the Temple of the Warriors at Chichén Itzá belong to the period of Toltec influence, from 1000 to 1200 A.D. They depict scenes from the conquest of the country by the Itzá. These pictures definitely show an attempt to depict the landscape realistically, and to convey an impression of spaciousness.

Mural paintings are also found in a number of buildings in the Maya ruins of Tulum, in Quintana Roo. They represent mythological scenes. The Tulum buildings are dated after 1000 A.D.

Another mural, which belongs to the last centuries before the Spanish conquest, decorates one of the rooms in the temples of Malinalco, in the State of Mexico, 25 miles south-southeast of Toluca. It represents a procession of warriors, armed with lances and shields.

Painted Books.—The miniatures contained in the painted books form an important aspect of Indian art; comparable on the one hand to the great art of mural painting, and on the other to some types of decorated pottery. Some of the miniatures show exquisite composition, drawing, movement, and coloring. They were painted on deerskin or on bark paper, dressed with white chalk. They deal with the calendar, ritual, mythology, and history. None of the picture books which have been preserved seem to go back further than 1000 A.D. Nevertheless, remains of similar books, consisting of heaps of alternate layers of thin chalk and powdered paint, have been found in tombs that are several centuries older.

The few pre-Hispanic codices which have survived the ravages of time and men are classified stylistically as follows:

(1) Aztec: The most important of these, from the artistic point of view, are the sections of the *Codex Borbonicus* which deal with the divining calendar and with the ritual of the months.

(2) Historical Mixtec: This group comprises a number of codices, which contain genealogies of Mixtec lords, and depict their acts of prowess.

(3) *Codex Borgia* group: This consists of codices which deal with the calendar, astronomy, divining, and mythology. The codices of groups 2 and 3 are firmly drawn and vividly colored, and differ only slightly in style. According to the art expert Salvador Toscano, this slight difference may be due to their different content.

(4) Maya: These are characterized by freedom of drawing, sensitiveness of line, and by the elegant sophistication of Maya art.

Decorated Pottery and Lacquer Work.—The pre-Hispanic potters did not know the potter's wheel. They usually shaped and modeled pots by hand, but they were also acquainted with the use of molds. A large number of techniques were used to decorate pottery. Due to limitations of space, only three types of decorated pottery will be discussed here: the painted pottery of Tlaxcala, Puebla, and the Mixtec region, produced after 1000 A.D.; the ritual champlevé-decorated pottery of Teotihuacán, produced between about 300 and about 700 A.D.; and stucco-decorated pottery, which is related to lacquer work.

The Mixtec-Puebla style employed in painting polychrome ware is identical with the style used in painting murals and codices in the same regions. The ware is decorated with figures of gods and animals, and with symbolic or simply decorative motifs painted in purple, orange, yellow, blue-gray, white, black, and other colors, and burnished to a high gloss.

The ritual vases of Teotihuacán were often first painted solid deep brown or brownish red, then polished and fired. After firing, the background was scraped away with some sharp instrument, leaving the figures outlined in silhouette and slightly raised above the scraped surface. Details within the silhouettes were shown by incising. The dark colors and brilliant finish of the unscraped portions contrast sharply with the mat background, showing the natural color of the clay or painted with cinnabar. Though not painting, the technique produces the effects of painting in two colors. The figures of gods, priests, religious symbols, and the like used to decorate this Teotihuacán champlevé pottery are the same as those painted in the great murals of the site.

Stucco decoration was applied after the vessels were fired. Two different techniques were in use. The first, called *paint-cloisonné*, was used mainly in western Mexico. A thick coat of paint was first applied over the entire surface of the vessel. This base was scraped to form depressions, and these were filled with the different pigments to be used in the composition. The areas of paint thus imbedded in the base were separated by narrow ridges, in which the base showed through, and which outlined the motifs. In the second technique, successive layers of paint were applied over the vessel. Parts of each layer were cut away to show the portions of the lower layers intended to form the design. Available evidence indicates that this second technique is older than the other. It was used in central and southern Mexico and in Guatemala. It seems certain that some organic adhesive or solvent was used, in both cases, to fix the colors.

These two pre-Hispanic stucco techniques employed to decorate pottery are similar to the lacquer techniques still used in Michoacán and Guerrero to decorate gourds or wood. In Michoacán, the *paint-cloisonné* technique is used, with a varnish made from an insect (*Coccus axin*). In Olinalá, Guerrero, the technique of successive layers is employed, with oil from the lime-leaved sage (*Salvia hispanica*) as the solvent medium. Furthermore, Gordon Ekholm found remains of gourd vessels with *paint-cloisonné* decoration in his excavations in Sinaloa. It cannot be doubted that much lacquer work was done on gourds and wood, but that the perishable nature of the material has made preservation very rare.

Monumental Sculpture.—The majority of pre-Hispanic sculptures were conceived either in terms of compact blocks, or pictorially in two dimensions only. The representation of mass in the three-dimensional terms proper to sculpture is rare in Indian art. The development of a true sense of space in sculpture was inhibited, in some cases, by technical inability to liberate form from the stone. In such cases, the sculptor surrendered to the material. In others, the lack of a true sense of space is due to either conscious aesthetic considerations which conceive form as a closed-in unitary whole, or to functional reasons. A large part of pre-Hispanic stone sculpture was conceived as an integral part of architecture. Therefore flat or low-relief carvings are more frequent than sculpture in the round. However, the same flat conception is found in minor sculpture in baked clay or precious stones; though modeled in the round, these figurines were intended to be seen only from one side.

The so-called *danzantes* (dancers) belonging to the earliest period of Monte Albán are either figures incised on slabs or flat reliefs. In these, the

ngures were made to stand out slightly by carving out the background, though no modeling of any kind was attempted. They represent unusually animated human figures, and are attributed to the beginning of the Christian era or a little before.

The oldest stone sculpture in central Mexico is that of Teotihuacán, dating from about 200 to 500 A.D. Teotihuacán sculpture is wholly conceived in architectural terms; its forms are massive cubes with a minimum of modeling. The reliefs of the Temple of the Plumed Serpent at Xochicalco, Morelos, show greater freedom of form, combined with a more sensual and whimsical style. They are attributed to the 9th century A.D.

The main works of sculpture in the ruins of Tollan (modern Tula), the Toltec capital, are flat reliefs on the fronts of the great pyramid and on the pillars of the portico of the temple. Even the colossal warriors which also supported the portico, though carved in the round, were sculpted following the techniques employed in flat relief. The Toltec period dates are from about 900 to about 1200 A.D.

Only during the last centuries before the Spanish conquest did monumental sculpture reach its zenith in central Mexico, both in quantity and quality. There exist remarkably realistic, austere, and expressive works of this period. Some achieved great economy of form, such as the head of the eagle knight, in the Museo Nacional de Antropología in Mexico City. Others are noteworthy for the sense of movement achieved within a compact block and for their plastic modeling, such as the figure of Quetzalcoatl in the Musée de l'Homme in Paris; or the great Coatlicue, the earth goddess, in the Museo Nacional de Antropología, in which the abundance of detail and the sophistication of execution do not detract from the grandeur of the whole.

There are few examples of the sculpture of the Huastec area of northern Veracruz and of the adjacent zones of San Luis Potosí and Hidalgo. From the Totonac region, north central Veracruz, the reliefs of the site of El Tajín, carved between 600 and 900 A.D., are noteworthy. Sculptured stone yokes, the so-called palmate stones ("palmas"), and flat stone representations of heads or complete figures in profile are also called Totonac, especially when they bear characteristic scroll designs. However, the area of distribution of these objects is much wider than the historic Totonac area.

The Olmec area of southern Veracruz and western Tabasco is famous for its colossal heads, for monolithic altars carved with figures in high relief and for other sculptures from Tres Zapotes, San Lorenzo, and La Venta. Another masterwork of Olmec statuary, and one of the best pieces of ancient Mexican art, is the figure called *The Wrestler*. It represents a man dressed in a loincloth, seated on the ground, apparently stretching his shoulder and arm muscles. The statue is truly three-dimensional in conception and was executed with great mastery of form and movement. It was found in Minatitlán, Veracruz, and belongs to a private collector in Mexico City. The dating of Olmec sculptures remains controversial; nevertheless, there are grounds for dating them between 300 and 600 A.D.

In the part of the Maya area now in Mexico, Palenque, Chiapas, is outstanding for the quality of its stucco reliefs and stone carvings. The stucco decoration is executed in deeply carved relief, with an extraordinary plasticity of forms. The stone carvings are flat relief or slightly modeled low relief. They were painted, and are thus classifiable more as painting than as sculpture. The carvings of the altars of the Temple of the Cross (dated 642 A.D.), the Temple of the Sun, and the Temple of the Foliated Cross (dated 692 A.D.) are well known. During excavations made in 1952 a similar carving was found in a secret chamber in the Temple of the Inscriptions. This stone covered a monolithic sarcophagus in which a great personage was buried. Palenque art is characterized by its naturalistic style, the grace and refinement in the representation of human form and movement, and its decorative splendor. The carvings show an extraordinary sensitiveness of line. Paradoxically, the carvers of Palenque were not sculptors, but excellent draftsmen who, like Hans Holbein the Younger, and Jean Auguste Dominique Ingres, used line to produce the illusion of mass. Many carvings in flat relief or low relief cover the steles, lintels, jambs, and panels of other ruins in the Maya zone of Chiapas, Tabasco, and the Peninsula of Yucatán. These belong to the middle Classic or late Classic periods (about 500 to 900 A.D.). Later, Toltec influence reached Yucatán. This is exemplified by the carvings and sculptures of Chichén Itzá (about 987 to about 1204 A.D.).

The sculpture of Michoacán is known from a few examples only. They tend to be cubic in shape and are schematically and roughly worked.

Ceramic Sculpture.—Sculpture in Mexico begins with the hand-modeled figurines of baked clay belonging to the Archaic period, which lasted to about the time of Christ. The oldest ones seem to be expressions of a fertility cult, involving the symbolic use of female figurines. Many Archaic figurines are conventional in type and seem to have been produced according to standard formulas which did not permit much leeway for the expression of creative impulses. Nevertheless, in others the creative will of the artist is clearly visible, even within the established conventions. The tradition of sculptured clay figurines of religious character lasted in central Mexico up to the Spanish conquest. After the peak period of Teotihuacán, however, they were cast from molds, resulting in a series of conventional types of little artistic value.

In Oaxaca, clay sculpture consists mainly of funerary urns, with different styles corresponding to successive periods. The most abundant of these are of the epoch Monte Albán III (400 to 700 A.D.). These funeral urns of Monte Albán III are heavily structured and covered with ornamentation which had ritual meaning.

In the Maya area, the older figurines of Jaina Island, off the Campeche coast, are small masterworks of realistic art. They are hand-modeled and represent warriors, priests, ballplayers, and women. They are dated at about 600 A.D. The Jaina figurines of a later period (roughly from 700 to 1000 A.D.) are mold-made and conventional in style; nearly all represent women and animals.

In western Mexico (Colima, Jalisco, and Nayarit) baked clay statuary achieved extraordinary development and artistic importance. These western ceramic sculptures are characterized by great economy of form. They portray psychological states with jovial irony. Although intended as funerary art, they faithfully reproduce scenes from everyday life. They may have been inspired by religious ideas, according to which life in the mansion of the dead was thought to be a continuation of life on earth.

Masks.—Masks of stone, wood, baked clay, and bone form an important aspect of pre-Hispanic

art. They were used in magic, and for religious and funerary purposes. During religious ceremonies, the priests covered their faces with masks representing the faces of the gods. In the representations of the gods, their faces are also often seen covered with masks. In funeral ceremonies, the dead body was completely wrapped in cloth, and a mask was placed on top of the bundle. The face of the personage buried in the secret chamber of the Temple of the Inscriptions, mentioned above under *Monumental Sculpture,* was covered with a mask composed of hundreds of jade tesserae pasted on a coat of stucco. The eyes of the mask were made of shell, with obsidian irises.

The use of masks is attested since Archaic times. Aesthetically, the stone masks of the Teotihuacán culture deserve special mention. They show great simplification of the features of the human face, but within a basically naturalistic conception. The absence of individuality is striking, especially since they were probably used to represent the faces of the dead in funeral ceremonies. The art expert Paul Westheim has said that they were not realistic representations, but plastic representations of a concept. There are also Teotihuacán masks of baked clay, painted in many colors, which form the basic element of great incense burners. These are made in the same style as the stone masks. Equally outstanding are the miniature masks carved in Olmec style from semiprecious stones such as jade or jadeite, real masterworks of lapidary art.

A few wooden masks have been preserved. These are covered with mosaics of turquoise, jadeite, shell, mother-of-pearl, and lignite. The British Museum in London and the Prehistoric and Ethnographic Museum in Rome have the best examples. Some are also found in the Museum of the American Indian in New York. There also exist masks made from the frontal portions of the human skull, which are covered with mosaic. The British Museum owns the best specimen.

Lapidary Work and Mosaic.—The pre-Hispanic craftsmen worked jade, jadeite, turquoise, obsidian, rock crystal, and other hard minerals. The most beautiful works of Indian lapidary art are little figures, little masks, and anthropomorphic votive hatchets of Olmec style, worked in jade or jadeite. The most famous work in rock crystal is the human skull in the British Museum. Jadeite, obsidian, rock crystal, and alabaster were also used to make vases. Examples are the jadeite jug in the shape of the water god in the Museo Nacional de Antropología in Mexico City; the obsidian vase in the shape of a monkey in the same museum; the alabaster vase also shaped like a monkey in the Bliss Collection, National Gallery of Art, Washington; and the rock crystal cup from Tomb 7 at Monte Albán, now in the museum at Oaxaca. Ear plugs, breast pendants, and other jewelry were also made from these materials. Turquoise was used in mosaic, together with jade, coral, shell, and other materials. The small mosaic pieces were generally glued on a wood or leather base, occasionally on bone or stone.

A number of the most outstanding mosaic works are mentioned above under *Masks.* To these should be added: the wooden helmet in the British Museum; the handles of the sacrificial knives in the British Museum and in the Prehistoric and Ethnographic Museum in Rome; the wooden vases in the British Museum and at Copenhagen; the discs in the Museum of the American Indian, New York, and those found at Chichén Itzá; and the two-headed serpent in the British Museum.

Wood and Bone Carving and Shell Engraving.—Due to the perishable nature of the material, few wooden carvings have been preserved. Enough are known, however, to give an idea of the remarkable craftsmanship of the pre-Hispanic wood carvers. A number of slit drums (*teponaztlis*) and skin-covered drums (*huehuetls*) have been preserved. These are decorated with mythological scenes. Also preserved are a number of finely carved ceremonial spear throwers. The most remarkable bone objects are the spatulate objects found in Tomb 7 at Monte Albán; they are decorated in Mixtec-Puebla style with calendrical inscriptions and mythological figures. In the Huastec area (the northern part of what is now the State of Veracruz), engraving was used to decorate shell gorgets.

Weaving and Featherwork.—The art of pre-Hispanic weavers is known only from descriptions by ancient authors, and from representations of textiles in painting and sculpture. The chronicles tell us about the types of fabrics produced, and the patterns used are clearly shown in the artistic representations. Cotton was used to make high-quality textiles; agave fiber to make coarse fabrics only. Pre-Hispanic featherwork won high praise from the chroniclers. The lack of feather ornaments in representations of art older than 300 A.D. seems to indicate that this craft developed only after this date. Feather ornaments were in great fashion during the Classic period. At the time of the Spanish conquest, feathers were used for headdresses, fans, and cloaks, and feather mosaic was used to decorate shields. Only a few pre-Hispanic examples of this delicate craft have been preserved. The most beautiful of these are the great quetzal feather headdress of Montezuma II, and a shield, decorated with the figure of a fabled animal, the *ahuitzotl;* both are in the Kaiserliche Schatzkammer in Vienna.

Metalwork.—The tradition of metalwork was of relatively recent development; it does not seem to antedate 900 A.D. The pre-Hispanic metalworkers used gold, silver, copper, and some tin and lead. They alloyed copper with gold, copper with tin, and copper with lead. The technical processes known were: hammering, casting, welding, gilding, plating, and inlaying. Castings were made using the cire-perdue (lost-wax) process, in which the mold is shaped around a wax model of the object to be cast. They employed the *mise-en-couleur* process to gild objects. This produced a gilded surface on copper-gold alloy of low precious-metal content. The surface copper was dissolved by treating it with acids (probably plant juices) and subjecting it to heat. Pieces which are part gold, part silver were produced by welding. Abundant use of filigree characterized the style of Mexican metalwork.

The first rank in technique and artistry was held by the metalworkers of the Mixtec region. The jewels found in Tomb 7 at Monte Albán and presently in the museum at Oaxaca (rings, necklaces, breast pendants, and so forth) are good examples of their excellent work. Copper and silver were both worked in Michoacán, but the artistic quality of this work is low. In Yucatán, during the Toltec period, the local artists used the technique of *repoussé* to represent animated scenes of the conquest of the Maya by the Itzá on discs of imported gold. These scenes have great artistic value.

17. COLONIAL AND MODERN ART.

Indian painting had very little influence on colonial painting. There were great differences between the two: while the former drew inspiration from Indian mythology and found expression in hieroglyphs and symbols, the latter was devoted predominantly to the Roman Catholic religion and, in common with all European art, favored the use of natural forms.

Mexican colonial art, which could more accurately be described as the art of New Spain, can be divided into four periods: primitive, comprising approximately the 50 years following the conquest of Mexico in 1521; renaissance, a reflection of European Renaissance seen through Spain, lasting a short 25 or 30 years; baroque, developed during the 17th and a great part of the 18th century; and lastly, the period of the neoclassic academicians, during the last years of the 18th century and up to the beginning of the struggle for independence in 1810.

Painting.—*Primitive Period.*—Although pre-Hispanic painting had no direct influence on the art of New Spain, paintings by Indian artists are found in the years following the conquest; however, they used the forms of European art brought over by the Spaniards.

The first school of painting was founded in the capital of New Spain about 1525, only a few years after the conquest, by the Franciscan friar Pedro de Gante; Indian painters like Cuauhtli, Xochitótotl, Xóchmitl, Marcos Cipac and others studied there. Very few of their works have been preserved, but we still have a portrait of Fray Domingo de Betanzos on wood, and the image called the *Virgin of Guadalupe,* probably painted by Cipac shortly before the middle of the 16th century.

The first mural paintings were done about the same time in the cloisters of monasteries, following the fresco technique. The names of the artists are unknown, but it can be safely assumed that in many cases they were Indians, directed by the friars, who found inspiration in European paintings and engravings. The subjects are sometimes simply Italian ornamental themes (so-called grotesque). The most important, however, are usually representations of religious subjects and images of Christ and the saints; although in an exceptional case (at Atotonilco, Hidalgo) the Renaissance influence was so strong as to prompt the reproduction of two great figures, those of Plato and Aristotle, in Renaissance costume. Good examples of this type of work are found in the monasteries of Huejotzingo, Puebla; Acolman, Mexico State; Actopan, Hidalgo; Epazoyucan, Hidalgo; and many others.

Renaissance.—It is perhaps not very accurate to call renaissance painters those who flourished in the last 30 years of the 16th century, but it would be difficult to find another name suitable for them; indeed, their painting is the same as that of the Spanish Renaissance, with its twofold Flemish and Italian influence.

Andrés de Concha, Juan de Arrúe (1565–c.1637), and Simón Pereyns were painters of this period. Pereyns, the most important, was Flemish, and his works belong to the Flemish Renaissance style. He was born before 1550, came to Mexico in 1566, and probably died at the end of the century. His work may still be seen at Huejotzingo; in *La Virgen del Perdón* (*Virgin of Forgiveness*), a good painting in the style of the 16th-century Flemish Madonnas, in the Cathedral of Mexico City; and in many other paintings.

The period which followed can be described as one of transition between renaissance and baroque. The outstanding painter was Baltasar de Echave y Orio, also called Echave el Viejo (the Elder; c.1548–after 1612). He was of Basque origin and came to Mexico at an early age in 1573. Echave's painting was done at the end of the 16th century and in the first quarter of the 17th. He borrowed from both Italians and Flemish, but the two influences never blended adequately. Echave used rich and intense colors. Some of his work is preserved in the Palacio de Bellas Artes in Mexico City. His son, Baltasar de Echave Ibía (1583–1640), has been called "the blue Echave" by Manuel Toussaint because of his marked preference for this color. Several religious paintings of his have been preserved, as well as the portrait of an unknown lady.

Of the same time were Sebastián López de Arteaga (1610–1656), a good portrait painter, and Alonso López de Herrera (d. about 1654), called "the Divine," who achieved great fame. The latter was talented and possessed a remarkable knowledge of his craft. He followed the Italian school; critics have pointed out the influence of Titian. Luis Juárez (fl. 1610–1630), a weaker but very prolific contemporary painter, had leanings towards mysticism. His paintings show certain traits which class him clearly within the baroque tendencies which began at that time.

Baroque.—Mexican baroque architecture is varied and rich, but baroque painting is not. The contrast is all the more remarkable because there is no doubt that baroque painting in New Spain came directly, almost exclusively, from Spanish painting, which reached its highest peak in the 17th century with such masters as Diego Velázquez, Francisco de Zurbarán, and Bartolomé Esteban Murillo. Evidently the distance was too great, and as a consequence painting in Mexico falls well below the Spanish level. The work of Mexican baroque painters was commonplace, a very weak reflection of the Spanish originals, whose excellence made them unattainable.

Baltasar de Echave y Rioja (1632–1682), grandson of Echave el Viejo, was one of the first completely baroque painters. He achieved dramatic effects through the movement which he put in the various elements of his paintings.

Among other painters of the time may be mentioned Juan Correa (c.1649–1738), Cristóbal de Villalpando (c.1649–c.1714), and the brothers Juan Rodríguez Juárez (1675–1728) and Nicolás Rodríguez Juárez (1667–1734), all of whom favored religious subjects, and make good use of color and light effects, with hardly discernible differences. Their painting, in true baroque fashion, is complicated and sumptuous, and they show a marked preference for a purely decorative and spectacular treatment.

The Mexican baroque entered a new phase in the 18th century, when the already few possibilities of expression were further reduced. Inspiration was still found in Spanish painting, which was also in a decadent state, after its great 17th

century. In Spain, the disciples of Murillo had turned his softness of color into a nauseous surfeit of tender pinks and blues. Such an evil example produced in Mexico an art of set formulas which prescribed rose-colored flesh, except in the case of ascetics, who were to be depicted as of yellowish complexion; carelessness in the treatment of robes; pitch-colored backgrounds, the better to show soft colors in the first planes; and several such defective methods, monotonously repeated. Two names should be mentioned in such a panorama, Ibarra and Cabrera. José de Ibarra (1688–1756) possessed good technique, but his use of color followed the trends outlined above. His self-portrait is among his best works. The reputation of Miguel Cabrera (1695–1768) as a good painter has come down almost to our times; the only explanation for this is to be found in a general decadence of taste, since his work was, to begin with, inconsistent—probably owing mainly to the great number of pictures he painted—and then, although his drawing was good, his composition was generally bad. All this apart from his sharing in the generally defective coloring of the aftermath of a great period.

Academicians.—The Royal Academy of San Carlos was opened in 1781 for the purpose of giving instruction in fine arts. It marked the end of a very decadent baroque, and its being replaced by neoclassicism. Two of the important painters that came out of this school before the end of the colonial era are José Luis Rodríguez Alconedo (1749–1815) and Rafael Ximeno y Planes. The former was an excellent silversmith and painter, but his output was small. His self-portrait in pastels is his best work. This is now in the Academia de Bellas Artes at Puebla.

Rafael Ximeno y Planes (1761–1825) was born in Spain, studied in Mexico and Rome, and came back to Mexico in 1795 to direct the academy. He painted many excellent portraits, such as that of the sculptor and architect Manuel Tolsá. He used oil for much of his work and tempera in some murals, like those in the cupola of the cathedral of Mexico City and the chapel of the old Mining College; there Manuel Toussaint found a clear influence of Giovanni Battista Tiepolo.

Sculpture.—*Primitive Period.*—The process is similar to that observed in painting: to begin with, Indians worked on European figures, and managed to leave in them a strong expression of their own sensitivity. The results were primitive and ingenuous pieces of sculpture, now revealing a certain childishness, now a certain ruggedness bordering at times on the monstrous.

There are some crucifixes left from those early times, which are carved in soft wood (patol), and are copies of Spanish originals. Some work was also done in papier-mâché.

We may also consider as sculpture the reliefs executed on the walls of monasteries and churches. These are mostly images of saints, symbols, or even purely ornamental shapes. There are good examples of this type of work in the monasteries of Calpan, Puebla; Tepoztlán, Morelos; Tlalmanalco, Mexico State; Yuriria, Guanajuato; and others. Like the frescoes done at the time, these reliefs seem to have been modeled on copper engravings or woodcuts of various origin.

Renaissance and Baroque.—Again there is a strong parallel with painting. The best of Spain's sculpture was done by Alonso Cano. Pedro de Mena, Juan Martínez Montañes, and others; in Mexico, sculptors filled church exteriors with carved stone figures, and the inside with numerous polychrome or *estofado* wooden sculptures. *Estofado* sculptures are wooden images covered with stucco or plaster, on which gold leaf is applied. Lines are drawn on this with a burin and colors are sometimes applied on top.

Architecture and sculpture blended in wonderful, frequently gigantic reredos which were usually made in three tiers with a finishing motif at the top, a central panel and from two to four panels on each side. They contain oil paintings and sculptures inside niches. Each part was usually executed in a different architectural style. The sculpting work, done by different persons, covered every bit of available space—thousands of columns, friezes, cornices, brackets, all of it carved in wood and lined with gold leaf; here indeed is the glitter and light and shadow play typical of baroque fancy.

The first reredos were in the richly ornamented plateresque style, following the Renaissance influence; among these are the ones at Xochimilco near Mexico City, and, better still, at Huejotzingo, Puebla, executed by Simón Pereyns. But the great period of reredos came later, in the 17th century, when the full influence of the baroque was felt. In all of them we find twisted columns, fewer paintings, and a greater number of sculpted figures; they are full of garlands, angels, symbols, all of them admirably carved and in great profusion. The Churrigueresque type in the 18th century gave sculptors and wood carvers their boldest conceptions, the result being such masterpieces as the reredos of Tepotzotlán, Mexico State; Querétaro; and Salamanca, Guanajuato.

Academicians.—In delivering the *coup de grâce* to baroque art, the Academy of San Carlos put a stop to the development of reredos; but, perhaps as a compensation, it was then that statuary received full attention, just because then each statue began to be considered as an end in itself, not as part of a great mass of a reredos, where each statuette, engulfed in the great mass of decor, lost its identity.

Puebla and Querétaro were the two centers of sculpture in the last years of the viceroys. The names Cora and Villegas became famous in Puebla as those of two families that gave several well-known sculptors; the outstanding ones in Querétaro were Mariano Arce and Mariano Perusquía. A great architect of Celaya, Guanajuato, Francisco Eduardo Tresguerras (1759–1833) also executed a number of sculptures.

The best sculptor of the academic movement in Mexico was Manuel Tolsá (1757–1816), also an architect, whose equestrian statue of the Spanish king Charles IV, in bronze, is preserved in Mexico City as one of its most beautiful and appreciated monuments.

Minor Arts.—Native precursors are of importance in some of the minor arts, such as silverwork and feather mosaic. The decadence of the last dates from early times and it is now almost lost. Otherwise the native element took refuge in popular arts like ceramics, the Michoacán and Guerrero *jícaras* (wooden bowls), and few others. In the majority of cases, however, the European arts became predominant, and even materials and tools were imported.

As was to be expected, the development followed closely the growth of the colonial regime. The increase in population and wealth, the growth

of the cities—above all the capital city—the luxury and pomp of the wealthy classes, the baroque leaning to ostentatiousness and flamboyance, all these favored the development of industrial art in the 17th and 18th centuries. Since such arts vary according to regional and personal characteristics, it is possible to come to know them only through very specialized studies. It is sufficient here to say that they were carefully fostered in New Spain. Jewelry, ornaments, and religious objects of the highest class were made of precious metals, and many Mexican towns still show with pride their iron and bronze grillwork, locks, ancient arms, and other objects. As for woodwork, fine carved furniture and inlaid work in ivory, tortoise shell, bone, and silver were made. Among luxury goods, fine work was done in dyed or gilded leather cordovan and *guadameci* (embossed leather), as well as in weaving and embroidery. Ceramics were also prominent, ranging from that which originated in the pre-Hispanic past to that inherited through Spain from the Arabs, such as the Talavera style of glazed tiles developed at Puebla. The Museo Nacional de Historia and the Museo de Arte Religioso in Mexico City, the Museo José Luis Bello in Puebla and other regional museums, as well as many private collections, have abundant examples of such crafts.

19TH CENTURY ART

Because of the troubled beginnings of independent Mexico, artistic activities were at a very low ebb. The plastic arts lived on the remains of colonial art, creating nothing new. It was not until 1839 that steps were taken to reorganize the Academy of San Carlos. Two Spanish masters, the painter Pelegrín Clavé and the sculptor Manuel Vilar, were engaged to effect a reform in the plan of studies, and arrived shortly after.

Apart from his work as a teacher and director, Pelegrín Clavé (1810–1880) also painted a number of pictures which were well liked. He arrived in Mexico in 1846 to assume the directorship of the Academy of San Carlos, and his influence was instrumental in bringing about a change, indispensable at the time. He did not limit his work to religious paintings, but drew inspiration also from history and fiction. In his portraits he strove for likeness to the model, using gay, brilliantly colored silks and velvets which replaced the monotonous dark shades that obtained in colonial times. In so doing he followed the style whose principal exponent in Europe was then Jean Auguste Dominique Ingres.

The most promising of Clavé's students, Santiago Rebull (1829–1902), Felipe Gutiérrez (1824–1904), and José Salomé Pina (1830–1909), were sent to continue their studies in Rome, and their work was admired in several exhibitions given in Mexico between 1850 and 1865. Ramón Sagredo (1834–1872) and Juan Cordero (1824–1884) are of the same school, though they belong to a later period; also, toward the end of the century, Luis Monroy and Félix Parra (1845–1910). All of them painted portraits, and historical and religious paintings. Their asset was a thorough knowledge of their craft; their handicaps those of the academic movement: limitation, lack of vitality, artificiality, and conventionalism.

It was also a Spanish master, Manuel Vilar, who, coming to Mexico with Clavé in 1846, gave a new impulse to sculpture. His stay in Mexico was shorter than that of Clavé, but during it he endeavoured to teach correct academic sculpture. His most proficient students were Miguel Noreña and Gabriel Guerra (1847–1893), who made several praiseworthy pieces. They worked together on the monument to Cuauhtemoc which is now in the Paseo de la Reforma in Mexico City; Noreña made the hero's statue, and Guerra the four high reliefs adorning the base. The five pieces are in bronze.

Landscape painting in Mexico was begun in the second half of the 18th century, when the Academy of San Carlos arranged for the Italian landscape painter Eugenio Landesio to come to Mexico to teach his specialty; this he did for some 20 years. His most outstanding student was José María Velasco (1840–1912), whose works are mostly landscapes. Velasco always kept to a high standard of achievement and some of his paintings are of the very highest quality; of these are two large canvases of the Valley of Mexico, which are in the Museo de Artes Plásticas.

In 1903 the Catalan painter Antonio Fabrés was appointed to direct the academy. Under him Mexican painting continued along the decadent way it had again fallen into, by following the mistaken road of "photographic" realism, with certain leanings toward the French manner. Two artists are perhaps worth mentioning: Leandro Izaguirre (1867–1941) and Julio Ruelas (1871–1907). The second was an extremely capable but warped draughtsman.

Jesús F. Contreras (1866–1902) should be mentioned among the sculptors of the time. In spite of the loss of an arm, he executed a number of statues for the capital and other cities of Mexico.

Meanwhile, some Mexican artists who were studying in Europe and others who had stayed in their own country were venting their dissatisfaction with the state of the arts. These fostered the awakening of the movement which was to bring far-reaching changes not long after. But very few people then realized that the most important artistic effort was being made in a small printing workshop that was publishing stories, prayers, plays for marionettes, and *corridos* (popular narrative songs) in leaflets and sheets that were sold for two or three centavos. Woodcuts and copper prints had been made in New Spain since the 16th century. The first lithograph press was founded in 1826, shortly after independence had been won, and that type of work was assiduously cultivated during the 19th century.

Manuel Manilla (1830–c.1890) and José Guadalupe Posada (1851–1913) were doing their work for the publisher Antonio Vanegas Arroyo in Mexico City, illustrating with their engravings that genuinely popular literature. Posada's engravings, though showing the influence of Francisco José de Goya and Honoré Daumier, have such a strong Mexican character and such extraordinary strength and emotivity that they are, without a doubt, the best product of Mexican art in the 19th century. They not only announce the following period; they link up with it.

MODERN ART

The last European art movement whose influence was felt in Mexico was the impressionist—very strong in Europe and fully a 19th-century movement; very weak in Mexico and felt rather late. Among Mexican artists, it was best known to Alfredo Ramos Martínez (1875–1946) and Dr.

Atl (1877–), both of whom had lived for many years in Italy and France. They imparted their knowledge to young Mexican painters in 1910, and the result was, not an impressionist movement in Mexico, but rather the desire to seek some reform, something new and different.

Joaquín Clausel (1885–1936), a young landscape painter of great sensitivity, was the best exponent of impressionism in Mexico. Another young painter, Saturnino Herrán (1887–1918), used impressionist trends blended with a national feeling for subject and color, suggesting the discovery of a type of art of his own; unfortunately, he died before he could bring it to fruition.

Meanwhile the revolution had broken out, and during the most active years, 1914–1916, the political struggle and the battlefield demanded everybody's full attention. Some artists were abroad; others, like Dr. Atl and José Clemente Orozco, had embraced the revolutionary cause and were waging their own war, using their art as a weapon through political newspapers. Such an upheaval as the revolution brought about had of necessity to result in something new; it would have been impossible to return to the old ideas and forms of expression.

When peace came in 1921, a cultured and intelligent man, José Vasconcelos (1882–), was appointed minister of public education. Vasconcelos sought above all to create, and in this endeavor he saw fit to offer new opportunities to artists, making available to them public buildings which they could brighten with their artistic imagination.

Diego Rivera had been living in Europe from the first years of the century, having gone there after being awarded a scholarship by the academy, but he had returned to Mexico at the time of Vasconcelos' accession to the ministry. Together with Xavier Guerrero (1896–), Alva de la Canal, Jean Charlot (1898–), David Alfaro Siqueiros, Orozco, and others, he formed the Syndicate of Painters and Sculptors, and prepared to decorate the old and new buildings that the government was making available. They decided to do fresco or encaustic paintings on walls, to make them easily accessible to the common man and to prevent their being shut up in halls, like the oils and watercolors of old. In sculpture, they abandoned bronze and plaster casting, preferring to carve stone in the footsteps of pre-Hispanic sculptors. Thus was born that interesting phenomenon, perhaps the aspect of modern Mexico best known to the non-Spanish-speaking world, its postrevolutionary art.

Each artist followed his own path, all of them different. Some disappeared; others went on, growing in stature. The original group was followed by another, and a third group of artists began its career toward the middle of the 20th century. It is, therefore, inconvenient to follow the process as a whole; to avoid confusion it is best to refer individually to each of the artists that deserve to be mentioned within the strict limits of this short study.

Rivera.—Diego Rivera was born at Guanajuato in 1886. He studied at the academy in Mexico City and went to Europe in 1906, remaining there until 1921, except for a short visit to Mexico at the time the revolution was beginning. He worked in Mexico after 1921, except for visits to the USSR and the United States, where he did some paintings in the cities of San Francisco, Detroit, and New York. He tried various styles and used several techniques in his early days (realism, impressionism, and cubism; oil, tempera, and collage), but his important work began in 1922, and must be studied in two great sections: murals and easel paintings.

Rivera painted his first mural in 1922 in the Anfiteatro Bolívar of the Escuela Nacional Preparatoria in Mexico City, using encaustic paint. It has a vast theme of Man, Nature, and Life. The composition is excellent, but in the subject's treatment one can detect strong Italian and Byzantine influences. A short time later he decorated the ground floor of the Secretaría de Educación Pública (Public Education Department) also in the capital. It is here that social themes and subjects based on the Mexican Revolution of 1910 make their first appearance. In 1927 Rivera painted murals on the walls and vaulting of the former chapel (now the Escuela Nacional de Agricultura) at Chapingo, northeast of Mexico City. The subjects were land and the agrarian reform; the composition as well as the use of design and color are excellent. It can be said without hesitation that the Chapingo frescoes are Rivera's masterpiece, which he has been unable to surpass. After 1929, he devoted his frescoes in the Palacio de Cortés in Cuernavaca and the Palacio Nacional in Mexico City to subjects taken from the history of Mexico and the coming socialist revolution. He repainted, in the Palacio de Bellas Artes in Mexico City, the fresco that he had started—and had been forbidden to finish—for Rockefeller Center, New York. More recently, he has been engaged almost exclusively in trying to make a grand apology for Mexican cultures before the coming of the Spaniards. Through political ideology, he has fallen into practicing the art of propaganda.

His easel paintings, nearly always oil on canvas, show more varied qualities. He has painted popular Mexican types, portrayed with great dignity and devoid of picturesqueness; some landscapes; some life studies; and many portraits. They are in museums and private collections, mainly in Mexico and the United States.

Orozco.—José Clemente Orozco was born at Zapotlán, Jalisco, in 1883, and studied at the academy in Mexico City, where he died in 1949. He made cartoons and illustrations for some of the revolutionary papers, and later held an exhibition of paintings and other small works. Like Rivera and several other Mexican painters, he took to mural painting in 1922 and after that date his important work was in his frescoes, though he also did a great number of works in oil and tempera, as well as drawings and lithographs. His most important murals are found in the following places: Escuela Nacional Preparatoria (1922 and 1926), the Supreme Court building (1940), and the Hospital de Jesús (1942), all in Mexico City; in the United States at Pomona College, California, and Dartmouth College, New Hampshire; the library at Jiquilpan, Michoacán; and the university, Palacio de Gobierno (Government Building), and Hospicio Cabañas (Cabañas Foundling Home) in Guadalajara. The three last were painted in or about 1938 and they are, on the whole, the best. Of special note is the fresco on the cupola of the old chapel of the Hospicio Cabañas. There is, besides, an impressive array of Orozco's oils, drawings, and other easel work, all of a very high quality.

Orozco cultivated a very personal style, which

is in some ways slightly reminiscent of expressionism, but the peculiar characteristics he imparted to it give it a character of his own. It is above all virile, austere, sometimes fierce; there is in it none of the voluptuousness often found in Diego Rivera's work, but on the other hand, it usually has much more strength and movement; it is dynamic in its subjects and treatment, and it moves the observer—just as Diego Rivera's style is static. Some critics have insisted that Orozco is the best Mexican painter of the 20th century. This is difficult to judge, however, when most of the other painters are still living and it cannot be said how or what they will paint in the future. Nevertheless, it can be definitely stated that Orozco was an inspired artist and a great master of the craft of fresco painting.

Siqueiros.—David Alfaro Siqueiros, born at Chihuahua in 1898, has lived a very full life as a Mexican revolutionary, a union leader, and a soldier in the Spanish Civil War, always fighting vehemently for the extreme left. He was one of the pioneers of modern Mexican painting. He has painted in North and South America, and his restless spirit has impelled him to try new materials and methods—undoubtedly in an attempt to modernize art, but it is difficult to see that the results achieved have justified such innovations. He has done murals and easel work, and his political passion has often carried him beyond the realm of art. There is no doubt that he is a good painter; but, so far, only a few portraits and human figures can be said to have lasting qualities.

The painters mentioned, and others who have followed them, are driven mainly by an all-pervading social consciousness: they accuse, they protest, they fight. This is certainly a most important aspect in much of modern Mexican painting, and it is an aspect which the outside observer and the foreign critic, Europeans especially, do not seem to comprehend—perhaps because they are steeped in a pure art tradition which is not part of the Mexican way of life.

Other Painters.—Painters whom we can call independent have worked alongside those who express social or political themes. Among them should be mentioned Francisco Goitia (1884–), who gave pictorial expression to the misery and grief of the poor; in the austerity of his *Tata Jesucristo* he has achieved one of the most dramatic paintings of modern art. Goitia is also a landscape painter. Doctor Atl (pseudonym of Gerardo Murillo; 1877–) is a prolific painter of strong and concise landscapes, using varied techniques. Manuel Rodríguez Lozano (1896–) has, with great intelligence and self-control, followed his own path in paintings of a strong poetic feeling allied to fine drawing and a sensitively quiet use of color. Rufino Tamayo (1899–) is undoubtedly one of the best Mexican painters, but the style he has cultivated since about 1940 has placed him nearer the modern international school and farther from Mexican painting.

There is a later group of painters which has been named the second generation of modern Mexican painting. Of these, the following have done outstanding work: Carlos Orozco Romero (1898–); Julio Castellanos (1905–1947), whose death before he could be said to have reached maturity cut short a highly promising career; Federico Cantú (1908–); Agustín Lazo (1900–); and Jesús Guerrero Galván (1910–).

In the last group, or third generation, are included those painters who are still young, but whose work is sufficient to reveal their talent. Among them should be mentioned Raúl Anguiano (1915–), Juan Soriano (1920–), and Ricardo Martínez de Hoyos (1918–). It is hardly fitting even to try to judge these painters, who are now in their prime and who, because of their age, are still susceptible to change.

Sculpture.—By contrast, modern sculpture, though starting at the same time as modern painting, in 1922, is still very far from achieving the development and fruition that accrued to painting. The experiment of the Escuela de Talla Directa (School of Direct Carving) was very interesting because of the return the school advocated to the straightforward, austere technique that had produced so many masterpieces in pre-Hispanic Mexico. But the results did not come up to expectations, nor was the experiment long continued. Some giant-size statues have been carved —the best example is the statue of José María Morelos on the island of Janitzio in Lake Pátzcuaro—but results have been bad in every case: witness the Pípila Monument in Guanajuato, among others. Mexican sculptors have followed various tendencies, from realism to abstractionism, and they have sometimes created work which is praiseworthy, but never really meaningful or talented. The phenomenon has a parallel in many other places; it seems that our times are not propitious to sculpture. The best known Mexican sculptors are: Ignacio Asúnsolo (1890–), Luis Albarrán, Carlos Bracho (1899–), Manuel Centurión (1865–1948), Federico Canessi, Germán Cueto (1893–), Mardonio Magaña (1866–1947), Luis Ortiz Monasterio (1906–), Juan Olaguíbel (1897–), Guillermo Toussaint, Guillermo Ruiz, and Francisco Zúñiga.

Engraving.—This art, which became so important in prerevolutionary days with José Guadalupe Posada, has continued in its various forms: wood, copper, etchings, and lithographs. It can be said that, like painting, Mexican engraving now holds an important place. The principal places where engraving is carried out are in Mexico City: the Taller de Gráfica Popular (Popular Printing Workshop); the Escuela de Artes del Libro (School of Book Arts); and the two schools dedicated to plastic art, that of the National University and the one supported by the Secretaría de Educación Pública (Public Education Department). Some of the best engravers are: Francisco Díaz de León (1897–), Leopoldo Méndez (1903–), Carlos Alvarado Lang (1905–), Alfredo Zalce (1908–), Abelardo Ávila (1909–), José Julio (1912–), Mariano Paredes (1912–), and Julio Prieto (1912–).

Photography.—Photography has also made a place for itself among the arts. In the first part of the 20th century two photographers did notable work: Lupercio and Guillermo Kahlo (d. 1941). Three great foreign photographers resided in the country between 1920 and 1930, Edward Weston, Tina Modotti, and Serge M. Eisenstein. Their influence stimulated Mexican photography and raised its standards. The most distinguished photographers of recent times have been: Emilio Amero, Manuel Alvarez Bravo and Lola Alvarez Bravo, A. Jiménez, and Luis Márquez.

FOLK ART

The art critic Justino Fernández, in *El arte moderno en México* (Mexico City 1937), has made the following statement which is still valid:

> The general characteristics which can be found in this popular Mexican activity are: a great artistic feeling, especially in so far as decoration is concerned; a high degree of vitality, as can be observed from the number of objects produced and attention to detail; a concern with method to such a degree that it looks like routine; and extraordinary fantasy. It can therefore be said that Mexico holds the third place, after China and Japan, as a producer of folk art.

The only possible classification of folk art, since it follows no school and shows no particular period of development, is according to objects and sometimes to its sources of inspiration. In the following the objects are referred to according to their importance.

Folk painting is found mainly in religious subjects, in small paintings on sheet metal or cloth called *retablos* (another meaning of the word—in English, *retable*—which is used to describe the ornamental pieces of architecture or sculpture covering walls at the back of altars in many churches), showing figures or scenes with great ingenuousness and sometimes with a certain graceful, almost childish clumsiness. A lot of nonreligious painting was done in the decoration of *pulquerías* (taverns where pulque, a popular drink made from the fermented sap of the maguey, is sold). This custom, however, has been almost completely lost.

Folk art finds magnificent expression in weaving. Fabrics are woven in many different ways and for many uses: tablecloths, serapes (woolen blankets to be worn), *rebozos* (scarves of cotton or silk), garments, and ornamental pieces. The techniques are nearly always of Spanish origin, and so are the designs, though in certain regions (Oaxaca, Chiapas, and Michoacán) native influence can be clearly seen in embroidery or colored fabrics. Weaving can be best classified according to regions, since costumes and their ornaments serve best to differentiate popular regional characteristics.

Lacquered goods—vessels, boxes, toys; sometimes furniture and other objects—are also of great interest. The principal centers of production are Olinalá in Guerrero, and Pátzcuaro and Uruapan in Michoacán. The process followed in Olinalá is as follows: scenes and ornaments are painted in color on a black base; or else one single color is applied, on which certain parts are scraped to suggest lacework. In Pátzcuaro it is usual to paint in several colors, nearly always on a black base. The practice of this art had almost disappeared, but it was revived and has become almost as important as it once was in the 18th and 19th centuries. In Uruapan, colors are rubbed into the wood, using black as the background, and the whole is covered with a damp-resisting lacquer.

Leather and iron are worked following the tradition of Spanish arts and crafts. There are slight variations due to the influence of national characteristics. The working of gold and silver, which became so important in vice-regal times, has disappeared in many parts. Gold is being worked following the traditional manner in Oaxaca; and silver in Taxco, Guerrero.

Furniture with regional characteristics, following popular designs and motifs, was being built as late as the 19th century. These designs have been widely used by mechanized industry, and for that reason have changed and lost value.

A great variety of pots have always been made of clay and glass. These continue to be made; as well as toys and other useful and ornamental objects of the same materials. Glass blowing is carried out with great success at Guadalajara and Mexico City. Pottery exists practically everywhere, but as is the case with weaving, takes on distinctive characteristics according to the region. Such peculiarities tend to disappear nowadays, owing to facilities for interchange—whenever a certain type of pot or decoration becomes fashionable, it is immediately imitated by potters whose production ought to have completely different characteristics.

The manufacture of cheap toys has reached into practically the whole country, and offers a very wide variety. Many materials are used—fired clay, wood, wire, rags, paper, cardboard, tin, wax, and even chewing gum—and they are turned out in every kind of animal shape, dolls, and all sorts of objects, most often painted over with strong, contrasting colors.

The human form, apart from being used in clay, rag, wooden, or cardboard puppets, is also borrowed for the manufacture of masks, which may represent comical, awe-inspiring, or grotesque faces, or skulls; sometimes also animal heads. The masks are often children's toys, but in some cases are intended to cover the faces of dancers or actors taking part in dances or religious plays acted during specific celebrations.

The human form is also represented in the so-called Judases, which are small or large cardboard or papier-mâché figures (some being six or more feet tall) to which firecrackers are attached. The "Judases" are burnt publicly on the Saturday of Holy Week.

Piñatas (clay pots covered with colored paper in the shape of animals, ships, stars, and the like) and the crèches or Nativity scenes, with their clay and wax figures made up to represent Biblical scenes or scenes of regional customs, are all expressions of popular art which take place around Advent and Christmas.

Candies are often made or decorated in ways which allow them to be classed as popular art. Perhaps the most remarkable are the small figures made of sugar paste, like *alfeñique* (boiled sugar candy of different colors) and other candies in the shape of animals and objects. Most often they are made to represent skeletons, skulls, and the like, and are made, bought, and eaten around All Souls' Day (November 2), when the so-called *pan de muerto* (bread of the dead) is also eaten in various regional varieties.

All the folk arts are very poor in the northern states and greatly varied in the central and southern ones. They have also tended to disappear, due to several reasons. Sometimes it is because of the mechanization of industry; sometimes because easier means of communication have tended to standardize the formerly different production of each region; sometimes because the growing market for such goods has made manufacturers anxious to please the taste of the majority of buyers, often foreign tourists who prefer picturesqueness and mistaken Mexicanized motifs to genuine decoration, which is usually more austere.

The ornamental motifs in these arts and crafts are usually flowers, birds, and scenes and objects taken from nature, stylized according to the taste peculiar to the region or the artist.

Sometimes they are geometrical shapes of ancient origin. In certain cases short legends are written —"Souvenir Of . . ." or proper names, and so forth. Very seldom is the human figure used, but a very usual subject is death, represented by various symbols or allegories: skulls, skeletons, bones, coffins, funeral processions, tombs, and the like, used in the manufacture of masks, puppets, toys, bread, and candy. The reasons for this—atavism, reminiscence of forgotten cults, the character of the people, their interpretation of life, everything that may have originated and may justify the preference shown for death in folk art—may be studied, perhaps, only through ethnological and historical research. It is sufficient for the present study to record the facts as related to art.

18. ARCHITECTURE. Pre-Hispanic Architecture.—In discussing pre-Hispanic architecture in Mexico one cannot limit one's field of interest to the present-day boundaries of the Mexican Republic, and hope to understand all the architectural manifestations of that period. This is due to the fact that the culture out of which it arose extended far to the south, while limited narrowly in its extension toward the north. Reference here will therefore be made only to the geographical and cultural area which archaeologists call Meso-America, that is, central and southern Mexico, British Honduras, Guatemala, western Honduras, and El Salvador.

There has been remarkably little excavation, considering the great number of monuments left by pre-Hispanic cultures. Thus only the first phase of architectural investigation has been completed: that of describing and classifying the known material in basic ways. The systematic study of techniques and of the development of forms, as well as the evaluation of styles and aesthetics, awaits the future.

Archaic Culture in Central Mexico.—The first architectural development with which we are acquainted in Meso-America belongs to the level of cultural development characterized by farming and pottery. Its technology, religious ideas, and patterns of urban association are characteristic of a very wide geographical area.

Cuicuilco.—The one well-preserved monument which belongs to this culture and which has been studied sufficiently is found in the Valley of Mexico, south of Mexico City, and is called the Pyramid of Cuicuilco. Shortly after its construction, apparently, the monument was covered over by a layer of basaltic lava, averaging eight meters in thickness. (One meter equals 3.28 feet.) This accounts for its relatively good state of preservation. The monument was excavated by Byron Cummings of the University of Arizona in 1922.

Despite the fact that the building is called a pyramid, it really consists of four superimposed truncated cones. These decrease in size. The first has a diameter of 135 meters, the last a diameter of 70 meters. The layout is oriented almost exactly along a north-south axis, with one end formed by a ramp and stairway leading up to the entrance. This solid construction serves as a platform for an upper construction of wood of which only traces remain. The body of the pyramid is filled with a mixture of clay and rocks, while the outside was faced with stones. Part of this facing is preserved in the upper portions.

The radioactivity of organic remains, analyzed by means of carbon isotope 14 (radiocarbon method) has yielded 600 B.C. as a possible date for the site.

Classic Cultures in Central Mexico.—*Teotihuacán*—The most important material remains of the new cultural horizon in the Valley of Mexico, a horizon which to some degree extended throughout Meso-America, and which is characterized basically by the formation of great urban centers, is the archaeological city called Teotihuacán. It is situated in a small valley, about 25 miles northeast of Mexico City, to the east of the Valley of Mexico and subsidiary to it. The development of the city may be dated very roughly between the 1st century A.D. and the 8th or 9th centuries A.D. Its beginnings tie into the Archaic culture; its terminal phase links up with the Toltec horizon by way of developments at Azcapotzalco, where its culture was carried on. While Teotihuacán has been studied intermittently since the middle of the 19th century, its methodical study by Manuel Gamio, Ignacio Marquina, Sigvald Linné, Pedro Armillas, and others has been under way only since 1922.

The city plan is laid out around a basic north-south axis formed by the Avenue of the Dead (*Miccaotli*), 55 meters wide, which compensates for the unevenness of the terrain by means of ascending tiers. The Avenue of the Dead is about 2,500 meters long, with indefinite limits toward the southern end. The main religious and secular monuments are situated close to the axis and perpendicular to it. Other streets also run parallel or perpendicular to the main axis.

The initial plan determined by these axes was followed rigidly throughout the city's growth. Lines not in harmony with it were avoided. Curved lines are completely absent. Axes also relate the complexes of ceremonial buildings to each other, but these relations do not serve to tie the whole into one aesthetic unit. On the contrary, each building group forms a closed-in unit with scant ties to the other groups.

The main axis, the Avenue of the Dead, is cut off at the extreme northern end by the building called the Pyramid of the Moon. In front of this building the big avenue widens into a rectangular plaza, 150 meters long along the front of the pyramid, and 120 meters wide. West of this axis rise the groups called the Temple of Agriculture and the Group of the Columns; east of it the Pyr-

amid of the Sun and the buildings which surround it. To the south lies the so-called Group of Superimposed Buildings, and, just before the avenue crosses the San Juan River, the one watercourse which traverses the city, is the Viking Fund Group. On the other side of the river, and virtually in line with the prolongation of the axis of the Pyramid of the Sun, lies the complex of the Temple of Quetzalcoatl, also called the Ciudadela (Fortress).

Due both to their location and dimensions, the most important of the buildings mentioned are the Pyramid of the Sun, the Pyramid of the Moon, and the Temple of Quetzalcoatl. The typical plan of these buildings erected for religious purposes consists of a base formed by the superimposed terraces which supported a small temple. None of the small temples have been preserved. The entire complex is surrounded by a platform on three or four sides. The Pyramid of the Sun, 64.46 meters high, with a square base 225 meters on each side, wholly dominates its surrounding platform. This relation has been inverted in the case of the Temple of Quetzalcoatl. The platform, with sides 400 meters long, is vastly larger than the pyramid, which measures only 40 meters at the base.

It has been possible to recognize three distinct periods in the development of these buildings. They are evident primarily in the evolution of the surfaces of the terraces which rise in layers to form the platforms. During the earliest period, the surface is a simple slope. The last step is represented by the architectural form called the "Teotihuacán panel." This consists of a rectangular compartment, outlined by a flat molding, which juts out over a sloping platform one third the size of the whole terrace layer. The inside may or may not be decorated with paintings as well as with sculptured forms. On the Temple of Quetzalcoatl, for example, the heads of two different types of serpents, evidently symbols of water deities, are arranged in strict order within a geometric design.

The system of construction employed in nearly all the buildings at Teotihuacán is very similar. Basically, it consists in heaping up earth, rocks, and adobe, together with retaining walls made of lava, into solid inner bodies for the pyramidal platforms. The retaining walls sometimes form a framework throughout the building. The panels with moldings that jut out are made of whole stone slabs which hold up the weight of the panel, and are faced with ordinary stones and lime stucco. Only the Temple of Quetzalcoatl has facings entirely of cut stones, which protrude into the body of the building.

The layout of buildings used as homes has received less study. It is possible, however, to distinguish buildings near the great temples, which seem to have been used by the priestly class. They show a quite systematic distribution of rooms, with porticos in front, around sunken courts intended for religious purposes. These courts were common to a number of housing units. The habitation area seems to have been very large, so that the large religious buildings formed only the center of an urban aggregate of great proportions.

Later buildings were generally superimposed on earlier ones, following either the vertical or the longitudinal axes of these buildings. The later buildings thus often hid the earlier ones wholly or in part. This custom was followed not only in the case of the great temples but also in the case of human habitations. It constitutes a characteristic common to all Meso-America.

Teotihuacán architecture is important not only in terms of itself, but also because it made its influence felt in such widely different areas as the states of Sinaloa and Tamaulipas in the north of Mexico and the highlands of the Republic of Guatemala to the south.

Cholula.—In pre-Hispanic times this city, now eight miles west of Puebla, was the most important religious and urban center in the Valley of Puebla. Few remains exist, since the colonial city was built over the ruins of the pre-Hispanic city. The most important monument, the main pyramid, was excavated systematically after 1931. As a result, five different architectural periods are known. Each period is characterized by a pyramidal structure of different size, each of which incorporated the pyramid of the preceding epoch.

The phases which stand out most clearly are I, II and IV. One must remember that I is the oldest and that at the time of the conquest the Spaniards found the pyramid unused and in ruins, during the last phase (V).

The structure belonging to phase I resembles in shape the Pyramid of the Sun at Teotihuacán, although its dimensions are obviously smaller. It measures 113 meters by 107 and is typically oriented toward the west, with a deviation of 17°. Five stepped terraces of structured pyramidal shape lead up to the topmost platform, which lies 17 or 18 meters above the surrounding terrain. Each stepped terrace is thus roughly 2.5 meters high.

The most outstanding characteristic of this structure is perhaps the special decoration of the panels which were later added to the slopes. These include polychrome paintings of greatly enlarged insect heads. In style and technique, they seem to be contemporary with the two earliest periods at Teotihuacán.

During phase II the building was completely covered over and its dimensions greatly enlarged. A side of its square base came to measure 190 meters. Its height of 34 meters was distributed among nine terraces, each shaped like a truncated pyramid, but each subdivided into 12 steps 0.30 meters high. The whole edifice thus came to represent a platform with stairways running up each one of its four sides. This continuity, which so strongly emphasized horizontal lines, is interrupted at only four points on each side where open-air drains from the platform above project vertically.

This monument is unique in Mexico, due both to the originality of its conception and to the maximum of emphasis on horizontal lines in its construction. No other building is known in which the same arrangement has been employed.

The works belonging to phase IV, the last phase of importance, cover the preceding ones and lend the edifice its present character. They are sadly ruined on the outside, but seem to have comprised two enormous terraces with sloping surfaces, separated by a wide passage on three sides, while on the fourth side one surface led into another and formed a single slope.

The dimensions of this pyramid are the largest found in any monument built in Mexico. It has a square base with sides 400 meters long and a height of 62 meters, nearly the height of the Pyramid of the Sun.

Transition Period in Central Mexico.—*Xochicalco.*—The ruins of Xochicalco are located 17 miles southwest of the city of Cuernavaca in the Valley of Morelos. From the cultural and architectural point of view, they seem to represent a point of transition between the Classic cultures and the Toltec period, both in terms of time, and in terms of their geographical location as a link between the cultures of the south and the Valley of Mexico.

In contrast to Teotihuacán and Cholula, the ruins are situated on the lateral spur of a mountain, the natural shape of which has been modified by five stepped terraces which tend to organize the terrain into horizontal levels and a surrounding area. The general layout of the terraced area follows a north-south axis 1,200 meters long and an east-west axis 700 meters long.

The top platform is reached by means of two walks formed by staircases which begin in the south and west. It measures roughly 300 meters by 200 meters, and supports the chief buildings of the city. The most important of these buildings in terms of location, state of preservation, and architectural style is located where the general axes of the city cross. It consists of one body, the profile of which is formed by a slope that covers two thirds of its total height, and of an unbroken floor which juts out over the slope and rises on a beveled cornice. The temple which rose on this platform seems to have had a similar silhouette, though only the part belonging to the slope has been preserved. The outside of the whole construction is finished with reliefs of cut and worked stone. These represent the undulating figure of a plumed serpent, which shelters seated human figures and the symbol of the new fire in its curves. A number of authors have called attention to the stylistic similarity of the human figures to Maya representations. Remains of polychrome stucco, which once completely covered architecture and sculpture, are found in different parts of the whole monument.

There are other monuments adjoining the terraces, which form true esplanades. The most interesting of these is the ball court, which in layout and front elevations shows similarities to the ball courts of Copán and Piedras Negras in the Maya area, and to the ball court of the Toltec city of Tollan (Tula).

In contrast to the metropolis of Teotihuacán, Xochicalco seen as a whole gives the impression that the planner, in striving to attain the shapes of stepped pyramids, has attempted to erect one gigantic pyramid. Its body is formed by the natural prominence of the hill of Xochicalco; its stepped tiers are defined by the surrounding terraces.

Toltec Period in Central Mexico.—The fall of Teotihuacán as a cultural center marks a profound break in the development of architecture on the plateau, though it does not imply a complete abandonment of the architectural forms and arrangements produced during the city's period.

Pottery shows a cultural continuation of the Teotihuacán period; in architecture this is represented by decorative elements which appear at Tollan and which were developed during the preceding period. Among the latter elements may be mentioned the special type of panel employed at Tollan (this represents the last step in the evolution of the panel of Teotihuacán and is described below); the merlons of battlements in the shape of a transversal section of a snail; the representations of Tlaloc, god of the rain; the general arrangement of the pyramidal platforms in religious structures; and the layout of courts surrounded by rooms in structures used as homes.

Tollan.—The city of Tollan, the modern Tula, located in the Valley of Tula in Hidalgo, was the center of the new cultural horizon. Excavations were carried on there sporadically after 1873, but systematic excavations were made only from 1940 to 1945. As a result a number of buildings of artistic and archaeological value are known, and proof has been obtained that this city was the capital of the Toltec Empire mentioned in the Indian chronicles before the Spanish conquest.

The building which gives the clearest idea of Toltec architecture is Temple B or Temple of Tlahuizcalpantecuhtli, which forms part of the northern side of the main plaza of the city. It consists of five superimposed terraces decorated with unusually shaped panels, which are divided into three horizontal strips. The lowest forms a slope roughly one third of the total height; the top one consists of a continuous frieze delimited by two smooth moldings with alternating figures of jaguars and coyotes. In the middle strip, panels which stand out alternate with sunken ones. These show eagles devouring human hearts, and a figure which combines human features with those of bird and serpent. A stairway on the southern side facing the plaza ascends to an upper platform where there are remains of columns in the form of anthropomorphic "atlases," eight of which held up the flat roof of a temple. The entrance to the temple was divided into three spaces by columns in the shape of serpents. The tail of each serpent formed a kind of capital, while the head formed the base. Three corridors of pillars, with square sections and decorated with the images of warriors, stood in front of this temple and connected it with the plaza.

All the decorative elements mentioned are repeated with remarkable exactness on the buildings at Chichén Itzá in northern Yucatán which belong to the period of Toltec influence. This supports the supposition that Temple B is older than the Toltec emigration to the south and Yucatán, which took place during the reign of Ce Acatl Topiltzin Quetzalcoatl, in the katun 2 Ahau (987–1007 A.D.), according to the Maya chronicles.

There are a number of other buildings, apart from the one just described. Among these are Mound A, remarkable for its size, but little known, and two ball courts, one on the western end of the main plaza, and the other north of Temple B. These ball courts are of undoubted importance within the general plan of the city and exhibit close similarities to the one at Xochicalco.

Other known buildings are the ones surrounding Temple B and the so-called Palace of Cielito which show the development of porticos around courts, with a layout similar to the buildings of Teotihuacán, but with greater use of isolated supports and more control over them.

Generally it may be said that Tollan lacks the monumental conception evident at Teotihuacán and Xochicalco. The principle of axes of a city has been lost, while the general orientation of buildings along a 17° deviation has been preserved. Religious architecture still dominates, but secular architecture has certainly gained in impulse and has come to use more differentiated elements, such as the pillar and the atlas-type

column. These are used to further a tendency toward relating architecture to the needs of interior structure and decoration, stripping it of the wholly external character typical of Teotihuacán.

The decorative sculpture on the buildings lends them an air of greater luxury and ostentation, retreating from the tendency of the preceding period towards the schematic and geometric. Yet the abundance of new decorative elements gives rise to the impression that there existed a creative tendency to produce new forms, without the refinement and control over aesthetic and technical expressions needed to carry these motifs to a high level of maturity.

Post-Toltec Period in Central Mexico.—*Tenayuca.*—In this small present-day village, eight miles north-northwest of Mexico City, and once of great importance as the center of Chichimec power after the eclipse of Toltec rule, there are some remains which have been well studied in excavations carried on by the Instituto Nacional de Antropología e Historia.

A series of successively superimposed architectural structures belong to an equivalent number of periods. From the earliest period to the latest, the layout used is always the same. It is characterized by three or four stepped terraces with more or less sloping surfaces, which support an upper platform with twin temples. These can be reached by way of a staircase divided in the middle by a double ramp.

Mention may be made of a type of low wall formed by closely spaced serpents which coil back upon themselves and surround the pyramid on the three sides of lesser importance.

The decorative and architectural poverty of these monuments and the repetition of the same arrangements seem to indicate a standstill in the evolution of styles during the three centuries preceding the Spanish conquest.

The known remains of the great temple of the old Aztec city of Tenochtitlán in Mexico City and of the temple there in the barrio (quarter) of Tlaltelolco resemble the Tenayuca pyramid in style.

Valley of Oaxaca.—*Monte Albán.*—This ancient city, six miles west of the modern city of Oaxaca, is primarily interesting for its overall plan in which the highest portion of a hill rising 400 meters above the valley has been used for its buildings. The main center includes a rectangular plaza surrounded by buildings on its two larger sides and delimited on the two shorter sides by two great platforms. The main axis of the plaza is marked by four low structures which stand in line. The principle of organization in terms of parallel or perpendicular axes is absent in this arrangement, which is characterized, however, by a series of relations set up by visual perspective which have determined the position and dimension of each monument.

The central part represents a great center of monumental buildings. The spurs of the mountain have been absorbed by means of stepped terraces, containing a large number of tombs. The whole complex is thus one great necropolis. Four periods of architectural development are recognizable in the form and system of construction of the tombs; these periods are also evident in the development of ceramics. The city flourished during the Classical period in central Mexico, and was abandoned about the end of the 8th century A.D., though it was used later as a burial ground.

The slopes of the stepped terraces of the main buildings are decorated with a special type of panel, called *escapulario,* used principally on ramps. It consists of alternating lower vertical elements and horizontal top ornaments of varying height.

Mitla.—This city, 26 miles southeast of Oaxaca, flourished during the Toltec period in central Mexico, after the decline of Monte Albán. The monuments of Mitla were known throughout the colonial period. They are preserved in part due to their stone construction which is, technically speaking, perhaps the best in Meso-America.

The city consists of five groups of buildings, clearly the same in layout. Each is made up of three extended constructions on top of platforms which surround a plaza on three sides, leaving the fourth open. These buildings bear decorations unique in Meso-American architecture. The decorations consist of three strips of panels similar to those found at Monte Albán, with square compartments containing Greek frets of great variety, which were produced by a type of stone mosaic. These buildings are also outstanding from the architectural point of view due to the use of great stone lintels on the doorways, and due to the division of halls by monolithic columns which held up the roof. The lintels are up to seven meters long and 1.20 meters wide.

Gulf Coast.—*El Tajín.*—This city, which flourished near modern Papantla in northern Veracruz during the Classical period in central Mexico, is not sufficiently known; but special mention should be made of its best preserved building, the so-called Pyramid of the Niches. The pyramid consists of six stepped terraces. Square niches, formed by laying flagstones vertically and horizontally, are crowned by a wide cornice. The effect of lights and shadows in the niches gives the onlooker an impression of great height and the total effect is very picturesque. The number of niches appears to equal the number of days in the solar year and there has been much speculation about their use. The general silhouette of the building has a slope of close to 45°.

Maya Area.—Maya architecture represents the most differentiated type of architecture within the entire cultural complex of Meso-America. Its stylistic development leads almost without interruptions from the beginnings of the 4th century A.D. to the middle of the 15th century. In terms of modern political geography, the monuments of Maya culture are scattered through Guatemala, particularly in Petén Department; British Honduras; the west of the Republic of Honduras; and the southeast of the Mexican Republic, which includes the Peninsula of Yucatán and the states of Chiapas and Tabasco. For methodological considerations, however, archaeologists divide the Maya area into the regions used below.

Petén Region.—According to the opinion of Sylvanus Griswold Morley (1883–1946), which is generally accepted, the first Maya cities to develop were Uaxactún and Tikal.

At Uaxactún, 37 miles north-northeast of the modern city of Flores, probably the oldest monument is the substructure E-VIII, excavated by the Carnegie Institution of Washington. It consists of a low stepped base with four stairs and ramps decorated with grotesque faces. The whole monument is covered over with a thick layer of stucco. Its construction is dated at earlier than

the Maya date 8.14.0.0.0. (317 A.D.), due to its association with Chicanel-type pottery. The construction above this base was of wood only.

One of the characteristic elements of Maya architecture, the corbeled arch, is found for the first time in Group A-V, dated a little later than 328 A.D. From this date on, it is used with variations in forms and materials throughout Maya architecture.

The prototype of the temple in the shape of a pyramid reaches its greatest development in the Maya city of Tikal, 27 miles northeast of Flores. There, five great structures were built, with the highest 70 meters high. The latter, Temple IV, consists of a stepped base of nine terraces and an upper construction of three chambers parallel to the façade, and walls up to seven meters thick, which support a cresting, 14 meters high, in the rear portion.

Copán and Quiriguá.—Due to the custom of setting up dated memorial steles observed in all the Maya cities, we know that Copán, 35 miles west of Santa Rosa in western Honduras, thrived from 450 A.D. to 800.

The architectural monuments show a more perfect type of construction, involving the use of cut stone and less use of stucco. Decorative sculpture made great use of human and animal forms, as well as of plant themes, and is found concentrated around doors and along the façades around archways.

The most important monuments are Temple 22, Temple 11, and the Stair of the Hieroglyphics. The first of these rises on a base formed by a single terrace and consists of two halls parallel to the façade, and two others perpendicular to the ends of the first two. The entrance leading from the outside into the first hall is formed by the mouth of a grotesque face; the communicating door between the first and the second hall is ornamented with human figures in high relief, which surround the door on all sides. A high step of the stairs is similarly decorated.

The Stairway of the Hieroglyphics begins at the east end of the main plaza. The fronts of its 63 steps are decorated with more than 2,500 hieroglyphics, and at every section sculptured figures rise from the center of the ramp.

The layout and the orientation of the buildings at Copán show some points of contact between this city and the cities of central Mexico. The Maya city of Quiriguá, in Izabal Department, eastern Guatemala, has little importance from the architectural point of view; its few buildings are patterned on those found at Copán.

Usumacinta River Drainage, Tabasco, and Chiapas.—Three of the most important cities of the Maya area are located in this region: Yaxchilán, Piedras Negras, and Palenque. Their general plan has been adapted to mountainous terrain; their urban pattern does not follow a clearly defined plan. The pattern consists of unequal terraces and steps, which tend to organize the terrain, and which create groups around plazas and courts.

Piedras Negras, in Petén Department, Guatemala, 90 miles west-northwest of Flores, is at one and the same time the most ruined of these cities and the richest of the three in the sculptured decoration of its steles, lintels, and thrones.

Yaxchilán, in Chiapas, possesses well-preserved buildings such as Structure 33. These consist of only one hall, which runs parallel to the main front, and transversal buttresses which support a large cresting formed by two wedged and leaning walls and which come together at the center of the building. The lintels of all of the buildings are stone and most of them are sculptured.

The Temple of the Sun at Palenque, State of Chiapas, Mexico, is its most representative structure. It is constructed of flat stones or flagstones and is thickly decorated with stucco. It has a double hall, and in the rear a small sanctuary with a corbeled arch which covers a panel sculptured in low relief. This panel shows human figures flanking a representation of the sun and four columns of hieroglyphics around the edges.

Southern and Northern Campeche.—These two regions are usually called Río Bec and Chenes respectively. They seem to represent an intermediate step between the architecture of the Petén region and the architecture of northern Yucatán.

The decorative forms of both groups are very similar. They make great use of the grotesque face. In the first of these zones there are simulated temples which do not contain any interior rooms whatsoever.

The most important cities of the first group are Río Bec and Xpuhil; of the second, Hochob, Tabasqueño, and Dzibilnocac.

Puuc in Yucatán.—In the north of the Peninsula of Yucatán there exist small complexes of cities and building groups which are notable for exact and careful stonework, for special types of decoration, among which geometric elements predominate, and for their stress of the horizontal lines in the buildings. It is possible that these buildings are coeval with Toltec influence, which is clearly evident from 1000 A.D. on, and which possibly began before that date.

The most important city for its size in puuc (Maya renaissance) style is Uxmal, 40 miles south of Mérida. Its general layout does not obey a strictly preconceived plan, but is clearer than that of most Maya cities.

The most important buildings extend horizontally and consist of corridors of rooms, raised on low platforms. Yet some also show considerable development into pyramidal structures, such as the chief pyramid, called the House of the Wizard, and also the structure called the House of the Old Woman.

Buildings with many rooms are almost always grouped in rectangular fashion: four buildings, the sides of which do not touch, around a court. To this type belong the so-called Nunnery Quadrangle, the House of the Doves, the Cemetery, and some others that are less well preserved.

The most outstanding building of puuc style is called the Governor's House. It is constructed on top of a platform with sides 150 meters long, and directly on a base seven meters high. The building proper consists of twin corridors of rooms with a front of 98 meters. The façade is divided into component parts. The middle one is the biggest. It consists of a flat area formed by the walls and a much-decorated higher area which belongs to the arches. Along this decorated higher surface geometric motifs, grotesque faces, and lattice work alternate along diagonal lines.

Remains of a ball court excavated by the Carnegie Institution's archaeologist, S. G. Morley, have also been preserved.

Toltec Influence in Yucatán.—The similarities between Toltec and Maya architecture became

known when systematic excavations were begun in 1940 in the Toltec city of Tollan (now Tula). According to Indian chronicles, corroborated by archaeology, this cultural current originated in central Mexico in the beginning of the second millennium A.D., although it seems certain that less profound contacts existed before.

The following architectural and urban elements are characteristic of this influence: layout of the entire city according to one plan, and more or less exact relationship of the axes of different buildings to each other; columns in the shape of plumed serpents; slopes at the base of walls; creation of great roofed-in spaces with corridors of pillars and columns; atlas-type figures; and use of merlons.

The buildings most representative of this influence are the Temple of Kukulkán (or El Castillo), the Temple of the Warriors, and the ball court at Chichén Itzá, 72 miles east-southeast of Mérida. The first two buildings have substructures which belong to an earlier period, but which also reveal Toltec influence.

In the same city there are other buildings which certainly belong to a previous period. These show more Maya style in their architecture, with grotesque faces as decoration, as is evident in the group of the Nunnery. These Maya elements continue in the buildings of the period of Toltec influence, together with the system of construction based on the corbeled arch.

Toltec influence is also visible in the much ruined cities of Mayapán, 24 miles south-southeast of Mérida, and Tulum, on the coast of Quintana Roo.

COLONIAL ARCHITECTURE

The architectural development of the colony shows various phases which are related in part to local conditions, both political and social, and in part to the development of styles in Europe. The first phase comprises the years from 1521 to 1550, a period which corresponds to the conquest of New Spain (Mexico). In the second half of the 16th century and at the beginning of the 17th century, Renaissance influences are felt; just as in the following years and during all of the 18th century the baroque style is developed to its ultimate consequences. The last 30 years of the colonial period reflect in Mexico the neoclassical tendencies current in Europe.

From 1521 to 1550.—Immediately after the conquest of the Aztec capital, Tenochtitlan, on the site of Mexico City, feverish activity was displayed to furnish the conquerors with churches and dwellings. In building the churches, the basilica type was adopted, as in the original cathedral of Mexico City. Another characteristic type was the so-called open chapel, which could accommodate the immense congregations of newly converted Indians, and which has certain analogies with the architecture of the natives. An example of this type of chapel open to the sky is that attached to the Monastery of Tlalmanalco, State of Mexico, which is arcaded; the arcades being profusely ornamented with sculptured archivolts in the plateresque style. Other examples are the churches at Actopan, Hidalgo; Yautepec, Morelos; and the Royal Chapel at Cholula, Puebla.

From 1550 to 1630.—During this period the building of great "fortress monasteries" belonging to the Franciscan, Augustinian, and Dominican orders was carried out. These edifices, springing up all over the country, served as active centers for the Christianization of the natives.

The general disposition of the monasteries is almost always the same. A thick-walled masonry church with a single nave, and rib vaulting supporting an arched stone roof was prevalent. Its exterior was generally undecorated except for the area around the entrance, above which there might be a small rose window. To the right of the church the monastery proper is found, together with one or two large patios around which are placed various dependencies. These constructions are surrounded by a great uncovered courtyard or atrium, which is enclosed by chapels and a battlemented wall.

It is easy to perceive in these monasteries the Romanesque, Gothic, and plateresque influences. The outstanding examples of this architectural type are found in the monasteries at Huejotzingo and Tepeaca, in Puebla; Acolman, Mexico State; Actopan, Hidalgo; and Atlatlahucan, Morelos.

In this same period the construction of great cathedrals, such as those of Mexico City and Puebla, was undertaken. These two edifices were not completed until the middle of the 17th century, however, and are predominantly neoclassical, although they incorporate many styles inside and out.

Baroque.—The monastic orders followed the expanding frontier of Hispanic civilization and were replaced in the rapidly growing cities by the secular clergy. The baroque style, which makes its appearance in Mexico after the first 25 years of the 17th century, coincides with the most flourishing economic period in New Spain and, due to its characteristics of form, it developed as the most suitable manner of expressing the amalgamated feelings of Spaniard and native. As a result the baroque style crystallized in Mexico into a group of works which, because of their number and quality, form the most genuine artistic manifestation of the colonial period, and at the same time constitute the most differentiated style when compared with the art of the mother country, Spain.

Within the baroque period, which maintained its output for more than 150 years, a line of evolution can be traced, which, starting from the forms of the Renaissance, began to develop a new style guided by the premises of expression and movement at all costs, until it reached the ultimate consequences of these principles.

The development of baroque style in Mexico is usually divided into two phases, the first of which is known as baroque proper and the second as Churrigueresque. Certain examples which show the proportions and regularities of the Renaissance combined with baroque principles are the churches of Jesús María, completed in 1621, and of San Lorenzo, completed in 1650, both in Mexico City. Toward the end of the century there appeared the ornamentation of the body of the columns, and finally the twisted or spiral column which forms the most typical element of this first phase. Church portals were heavily ornamented with carvings and a profusion of sculptured figures placed in niches. The interiors were also exuberantly decorated. Brightly painted, carved stucco covered walls and sections of ceilings with innumerable heads, figures, and varieties of decorative motifs. The baroque style was also adapted to large residences and colleges. Besides certain buildings erected in the capital, mention should be made of other groups

having definite local traits, such as the churches of the valleys of Oaxaca and Puebla, among which the churches of Santo Domingo in Oaxaca, San Francisco Acatepec and the Chapel of the Rosary in Puebla are outstanding.

Churrigueresque.—The second phase, typified by the almost exclusive use of the reversed pyramid as an ornamental support in façades and altars, appears for the first time in the Altar of the Kings of the cathedral of Mexico City. This altar, begun in 1718, is the work of Jerónimo de Balbos.

A great number of churches in Mexico City were built in the new fashion, which carried the baroque to its limits in fantasy and inventiveness and created even more elaborate church façades, and *retablos* (decorative altar pieces) of richly carved, gilded wood as a background to an array of small polychromed statues. Among such churches are the Sagrario Metropolitano and the Church of La Santísima Trinidad (both the work of Lorenzo Rodríguez), the Balvanera Chapel in the Church of San Francisco, the Church of La Santa Veracruz, and the Church of La Enseñanza. Churrigueresque extended itself to all corners of the colony and formed local focuses, the most important of which rose among the cities of the central regions. The finest examples of this style are the churches of Santa Rosa and Santa Clara in Querétaro, La Valenciana in Guanajuato, San Agustín in Salamanca, and the Del Carmen Church in San Luis Potosí, among others that might be mentioned.

In the final manifestations of baroque style the concept of architectural elements was lost; ornamental moldings, and animal, vegetable, and anthropomorphous leitmotifs being substituted for it. (See also the section *Colonial and Modern Art.*)

Neoclassicalism.—During the last quarter of the 18th century, in partial juxtaposition to baroque, there appeared the neoclassical style, imported directly from Spain with the arrival in Mexico of architects such as Manuel Tolsá, Antonio González Velázquez, Jerónimo Gil, and others. Tolsá, an architect and sculptor, and a native of Valencia, completed the cathedral of Mexico City and built the Real Seminario de Minería there. Of native architects, mention should be made of Ignacio Costera, Francisco Eduardo Tresguerras, designer of the Church of Nuestra Señora del Carmen in Celaya and the Palacio Real in Guanajuato, and José Manzo who worked mainly in Puebla. The neoclassical style did not terminate with the end of the colonial era, but lasted until the middle of the 19th century.

Domestic Urban Architecture.—This architecture, which showed far less variation than that of churches and public buildings, generally arranged rooms around a paved patio which was enclosed on four sides and contained the family garden, the rooms opening directly onto the patio. Most public buildings, of one or two stories, also incorporated the patio in their design. The houses, built of stone, stuccoed brick, or adobe, were usually severely plain outside. There were some notable exceptions to this, however, such as the Casa de Alfeñique ("Sugar-paste House"), built in Puebla in 1790, whose walls are faced with unglazed red and glazed blue tiles and a lavish white stucco trim, the latter giving the mansion its nickname.

MODERN ARCHITECTURE

To understand fully the development of modern architecture in Mexico, it is necessary to bear in mind its immediate antecedents in Europe, where its first manifestations occurred. These first manifestations appeared in Mexico in the middle of the 19th century, although they did not crystallize into a true artistic style until much later.

The 19th and Early 20th Centuries.—Whether one turns to the Europe of this period, or to Spanish America—in this case particularly to Mexico, where remarkable works of architecture were produced during the colonial period—a deep fracture becomes evident in a Western artistic tradition, which for an uninterrupted period of 5,000 years had produced an architecture in stone. The new architect, allowing himself to be carried away by a completely subjective taste, and utterly disdaining the deepest roots of style, turned to the latest artistic novelties exhumed by archaeologists and historians to find a repertory of anachronous forms which he applied with scientific coldness to the ornamentation of his façades. Thus an architecture was developed that copied the Gothic cathedral in building its churches, Greek temples in its banking buildings, and which even reproduced architectural forms alien to Western culture, such as Arabian patios and Mayan temples.

In this process of copying the forms of other arts, toward the end of the 19th century architecture reached a new phase characterized by the copying of nature itself; executing this copy not as a means of expression, but rather as a finality in itself. This is the artistic mode known as *art nouveau* (new art). The noble art of architecture, which fundamentally had expressed itself through the severe forms of geometry, now found itself transformed into an art of naturalistic ornamentation.

The situation in which architecture found itself was typified in Mexico by the arrival of two architects, Lorenzo de la Hidalga, a Spaniard who arrived in 1838, and Xavier Caballari, an Italian who reached Mexico in 1856. It must be noted that the period immediately following Mexican independence (1821) had marked a critical moment for the Academy of Architecture, which for a time was forced to close its doors and only regained impetus through the efforts of Javier Echeverría and José Bernardo Couto, chairmen of its Board of Trustees. It was they who decided to avail the academy of the services of de la Hidalga and Caballari.

Within the eclectic tendencies referred to above were executed the baldachin of the cathedral of Mexico City, which replaced the original one in Churrigueresque style, the Teatro Nacional (National Theater) inaugurated in 1844, and the dome of the Sanctuary of Santa Teresa. All three of these structures in the capital were the work of de la Hidalga and may be characterized as the last germination of that neoclassicalism which took hold in Mexico in the final years of its colonial period.

The Italian Caballari is important not so much for his personal output as because of the impulse he brought to the Academy of Architecture, modifying its curricula by fusing architectural and engineering studies into a single course.

The second half of the 19th century was dominated by influences emanating from France,

whence radiated the prevalent fashions and taste, not only in architecture but in other fields of life as well. The principal Mexican architects of the period were trained in the École des Beaux-Arts in Paris, bringing its teachings back to the academy in Mexico.

The architect Emilio Dondé (d. 1905) designed luxurious mansions and built the Church of San Felipe de Jesús in Mexico City in a style somewhat similar to Romanesque-Byzantine. Antonio Rivas Mercado, counted among the finest architects of his time, erected the Independence Monument in the Paseo de la Reforma in the capital. This not only ranks among the noblest architectural works of its period, but also served to introduce technical innovations, such as the use of supporting piles driven to great depths. These were introduced to offset the sponginess of the subsoil.

At the dawn of the 20th century another work of colossal dimensions was begun in Mexico City, the Palacio de Bellas Artes (Palace of Fine Arts). This was entrusted to the Italian architect Adamo Boari, who applied to it the forms of *art nouveau,* giving Mexico what is possibly the finest example of that architectural style in all the world; certainly the most finished. Boari's general layout is clear and well-ordered, and fineness of design and good proportions are notable in the details.

Other buildings of less importance were constructed in the capital in the most varied styles: the Edificio de Correos (Post Office Building), also by Boari, in Gothic; the pavilion of the Alameda de Santa María, in Spanish Moorish; and the Secretaría de Gobernación (Department of the Interior) in the style of the Renaissance.

In all these constructions, as in their counterparts in Europe, two new structural materials are made use of—steel and concrete. Nevertheless, the use of these did not yield, at the time, any apparent changes in the conception of architectural forms.

Contemporary Architecture.—Having examined the architectural production of the second half of the 19th century and the beginning of the 20th, one is able to investigate the architecture usually called modern or contemporary. A very brief reference to the aesthetic ideas which preceded it and which served to form the intellectual atmosphere in which it began will first be made.

The purely objective consideration of an artistic work is a tendency, based on certain of Immanuel Kant's philosophical considerations, which gained great momentum during the last third of the 19th century. In its historical application to the field of architecture it was championed by the German art theorist Konrad Fiedler, who saw the specific values of architecture as exclusively formal and spatial, the spatial ones deriving from the formal. Fiedler likewise maintained in his writings the basic predicate that the prime factor in architecture is "functionalism," considered as the need of covering an enclosed space. Similar ideas and even more radical ones were upheld by the eminent German architect Gottfried Semper, who proclaimed the technogenetic roots of architectural art.

Modern architecture rose out of the activity generated by these ideas, in the first decade of this century, some 15 years prior to its appearance in Mexico. It is necessary to refer to these ideas because of their widespread influence in contemporary Mexican architecture.

The first productions of modern architecture in Mexico were produced in the first interval of social stability following the Revolution of 1910. The head of the new architectural movement was a young architect, José Villagrán García, who attained the professorship of architectural theory in the National University in Mexico City and formed a small but integrated group with Mauricio R. Campos, Enrique del Moral, Juan O'Gorman, Juan Legarreta, and others, who soon became the stalwarts of the new architecture. This group contended against the Academy of Fine Arts, which they regarded as simply a follower of architectures of the past. According to the new ideals, architecture was to be eminently "functional" and was to solve the needs of man considered as a whole, in all his psychic and physical complexity.

Faithful to these ideas and in collaboration with his students, Villagrán García in 1925 brought to completion the laboratories of the Instituto de Higiene (Institute of Hygiene) in Popotla, a suburb of Mexico City, this being the first accomplishment of the new architecture in the republic.

The various blendings of ideas and a greater radicalism in their creative thought, together with the influence of the Swiss architect Le Corbusier, which was immediately felt by the pioneering group, moved O'Gorman and Legarreta toward a solution of the problems created by what were called "popular" dwellings of the masses. Together they began the construction of groups of "popular" homes and schools between the years 1931 and 1934. This architectural tendency, combined with ideas of a social and political nature, led to the creation of the so-called advanced school of construction by O'Gorman and the engineer José A. Cuevas in 1932.

Nevertheless, this appearance of modern architecture did not in the least suppress the great profusion of works representative of opposite ideas, among which mention should be made of the conceptions determined by the influence of the Paris Salon of Decorative Arts, and also of the various attempts to originate a "national" architecture. Among the first group mentioned one finds the works of Juan Segura, such as the Ermita Building in Tacubaya, a suburb of Mexico City, the open-air theater in Colonia Hipódromo, a residential section of the capital, and some of the works of Carlos Obregón Santacilia (1898–), such as the interior of the Bank of Mexico, also in Mexico City. In all these works may be noted the geometric stylizations of classical forms intermixed with surviving elements of *art nouveau.*

The attempts to form a "national" architecture have been of much greater importance, owing to the number of works those attempts have produced. The system followed in each case has always been to take forms or conceptions belonging to past periods of Mexican history and to adapt them to present needs and problems. In this fashion, the architect Amabilis brought to his constructions decorative elements of Mayan architecture from the Yucatán Peninsula. Obregón Santacilia adapted the typical dwellings of the 19th century, called *viviendas,* furnishing them with ventilation, illumination, hygienic conditions, and other modern improvements. In the reconstruction (1930–1934) of the Palacio de Bellas Artes, carried out by Federico

Mariscal (1881–), discreet use was made of pre-Hispanic themes, as in other constructions of the same architect.

In addition to these attempts, carried out by trained architects within the limits of discretion and archaeological knowledge, there have been other very numerous productions of private architecture and sometimes even of public buildings, executed generally by engineers and contractors devoid of professional skill. These productions, which have given a special countenance to certain entire residential sections of Mexico City, can be classified within the generic and derogatory denomination of Californian-colonial. In these productions one finds elements grotesquely copied from colonial architecture, profusely decorated with fireplaces, coats of arms, rustic touches, and the like. The most deplorable technical and structural qualities are combined with a taste that can only be described as ridiculous and anachronous.

Leaving aside those tendencies, which may be called heterodox, and once more taking up the new movement, it should be said that the most important fruits of modern Mexican architecture appeared during the decade of 1940–1950, brought into being in the large edifices built along the important avenues of Mexico City and in the great collective projects sponsored by various government agencies.

The first of the great privately owned buildings in the capital was that of the La Nacional Insurance Company, its design and constructions deftly carried out by the architect Manuel Ortiz Monasterio and the engineer Calderón. This type of building, similar in general outline to the skyscraper of the United States, has been also used in the constructions of the brothers Francisco (1894–) and Luis (1908–) Martínez Negrete who erected the San Antonio Building and the Seguros de México Building. Other great buildings have sprung up along the famous Paseo de la Reforma, giving this boulevard the definite quality of a commercial avenue. Among these the following should be mentioned: the building at Number 1 Reforma, designed by the brothers Martínez Negrete; the La Fragua Building by Mario Pani (1911–); and the vast central building of the Instituto del Seguro Social (Social Security Institute) by Obregón Santacilia.

Among the great groups of buildings designed for government agencies is the Hospital City in the capital, which is part of the general plan for the construction of hospitals in all parts of Mexico sponsored by Gustavo Baz while he was secretary of public health and social assistance, and which has been only partially completed. The design and construction of public schools throughout Mexico is also worthy of mention. This work is being carried out by the Committee for the Construction of Schools and by the Buildings Division of the Department of Public Instruction, under the direction of the architects José Luis Cuevas and Pedro Ramírez Vásquez.

Special mention should be made of the University City in the capital, begun in 1950 and dedicated in 1952. This work, of great transcendency from an architectural point of view, is the fruitful result of the collaboration of the best Mexican architects, headed by Enrique del Moral and Mario Pani, who are the directors of the project.

The formal characteristics of modern architecture in Mexico are very similar to the corresponding ones in Europe and the United States: elementary combination of geometrical volumes, a marked tendency towards a horizontal line, and an almost absolute exclusion of the curved line. When the latter is used, it is expressed mainly in the form of parabolas and ellipses.

Special attention is paid to the function which is to be fulfilled by the building, rationalist logic is applied to the use of materials and technique, and there is a growing interest in expressing a definite aesthetic idea. Any element that tends to obscure the expression of form is eliminated. Interior and exterior space is fused, not limited. All these are significant traits of modern Mexican architecture. Particular mention should be made of the importance granted by the Mexican architect to the use of colors as an element of ornamentation which underscores and gives added clarity to architectural form.

RICARDO ROBINA,
Architect.

19. LITERATURE. Mexican literature, like every other aspect of what we understand as Mexican culture, is not of a wholly indigenous nature. The roots of Mexico are found both in the native pre-Hispanic culture and in the Spanish culture. These two aspects have blended in varying proportions to form present-day Mexico.

Pre-Hispanic Period.—The most important pre-Hispanic peoples—the Maya, Tarascans, Otomís, Mixtecs, Zapotecs, and Nahuas; mainly the Aztecs among the last—all created important literary works, which undoubtedly were numerous. Unfortunately, these were almost completely lost when European civilization was superimposed on Indian cultures, for the native literatures were all oral and their creators had not yet perfected literary texts. Their hieroglyphs could express only concrete facts or symbols of concepts—thus all codices were records of history, taxes, or mythology—and they were useless to communicate that beauty of expression which is indispensable in literature.

Very few works were saved from the upheaval caused by the conquest, to be later transcribed into European writing; some books were, however, saved in this way, such as the Maya *Popol Vuh* and a few epic and lyric poems, mainly Otomí and Nahua, all of them relating to a period immediately before the conquest and all anonymous, with the exception of a few songs attributed to Nezahualcoyotl. Many modern scholars, however, doubt that this 15th-century king of Texcoco was the real author of these poems. In any case, these few monuments of a lost literature have exerted no direct influence in the awakening of what must now be considered as Mexican literature.

The true roots of the literature of Mexico are to be found in Spanish literature, in which at the time of the conquest (1521) one could already find outstanding examples of every literary genre, and which was soon to embark on its golden century, so amazingly rich.

The 16th Century.—The first type of work—not strictly literary—produced in New Spain (Mexico) was the chronicle. The best examples are found among the chronicles of the conquest, such as the *Cartas de relación* of Hernán Cortés and the *Historia de la conquista* (published 1632) of Bernal Díaz del Castillo, and among the religious chronicles—in those of the friars Toribio

Motolinía, and Jerónimo de Mendieta, whose *Historia eclesiástica indiana* (published 1870) is an account of the conversion of the Indian peoples to Christianity, and in the remarkable research work of Friar Bernardino de Sahagún, who wrote the *Historia general de las cosas de Nueva España* (first published 1829–1830).

Another primitive genre was the drama used for the evangelization of the Indians, which consisted of adaptions in the native tongues of the religious drama of medieval Europe. Its very purpose made it a short-lived phenomenon, to which many references are found but of which very few works are left.

A dramatic movement equivalent to that called *prelopista* (before Lope de Vega, 1562–1635) in Spanish literature soon made itself felt in the towns of New Spain where Spaniards lived, mainly in the capital. The year 1574 saw the performance, in honor of Pedro Moya de Contreras on his investiture as archbishop of Mexico, of the allegorical work *Desposorio espiritual del pastor Pedro y la iglesia mexicana* by the presbyter Juan Pérez Ramírez, the first writer born in Mexico (1543–?) and perhaps the first in the whole of the American continent. A short time later the *Tragedia del triunfo de los santos* was played. The author of this verse play with a medieval theme is unknown, but he was probably a Jesuit, and he shows a marked Renaissance influence. The most important writer of this time was Hernán González de Eslava (1534–1600?), of whom we have 16 *Coloquios espirituales y sacramentales,* religious and allegorical plays similar to the medieval mystery plays. They are uneven works, but the fact that some of them deal with local Mexican themes is of special interest.

Epic and lyric poetry were also cultivated from very early times. Francisco de Terrazas (c.1525–1600) was a good poet following in the steps of the school of Seville. Also important were Pedro de Trejo (c.1534–c.1600) and Fernando de Córdova y Bocanegra (1565–1589); but the outstanding writer of the period was Bernardo de Balbuena (c.1567–1627), who wrote three long poetic works: *La grandeza mexicana,* a eulogy of Mexico (1604); *El siglo de oro* (1608), a pastoral novel in imitation of Jacopo Sannazaro; and *Bernardo* (1624). The last, dealing with the semilegendary hero Bernardo del Carpio, is one of the best epic poems of its time.

Besides literary works in the Spanish language there were writings in the native tongues, decreasing in number as the years advanced; also works in Latin, of which the most important in the 16th century are some *Dialogues* (1554), descriptions of social and intellectual life by Francisco Cervantes de Salazar (c.1514–1575), a distinguished professor of the Royal University of Mexico (founded in 1551). Other prominent, though not so literary, writers are found among historians, jurists, physicians, mathematicians, and above all theologians, among whom the most important is the Augustinian friar Alonso de la Veracruz (1504–1584).

Baroque.—The great baroque period, the richest and most fruitful in New Spain, begins at the end of the 16th century and continues to the second half of the 18th. The literary genres already initiated were continued and developed in accordance with the basic characteristics of the Spanish baroque—superabundance, flamboyance, and dynamism.

After Balbuena, epic poems tend to disappear and none of them are really important; but the name of Arias de Villalobos, whose poem *Canto intitulado Mercurio* (1623) concerns the arrival of one of the viceroys, should be mentioned in passing.

Of special note is the case of Carlos de Sigüenza y Góngora (1645–1700), a remarkable author who wrote successfully in such varied fields as narrative (*Aventuras de Alonso Ramírez,* 1690); lyric poetry, of which he left many examples; history; geography; mathematics; and astronomy, with his bombastic explanation of a comet. But his most important work is a chronicle and compilation which he made on the occasion of two poetic competitions, and which he entitled *Triunfo parthénico* (1683).

The first important name in the baroque theater is that of Juan Ruiz de Alarcón y Mendoza. He was born about 1576 and studied in the Royal University of Mexico. He then went to Spain, where his dramas were played with those of Lope de Vega, Tirso de Molina, and other authors of the Spanish golden century. He was appointed to the Consejo de Indias (Council of the Indies) in 1626 and died in Madrid in 1639. Some of the most important among his plays are *Los favores del mundo, La verdad sospechosa, Los pechos privilegiados,* and *El examen de maridos.* Ruiz de Alarcón belonged to Lope de Vega's dramatic cycle in the Spanish theater, but had certain personal values, paying particular attention to form and the psychology of his characters. His influence was felt directly in the French classical theater, and he is surely, as Alfonso Reyes states, the foremost Mexican writer of international renown.

The remaining playwrights of the baroque period were much less important, but Eusebio Vela (1688–1737), a mixture of author, producer, and actor, should be mentioned. He did a great deal of work in Mexico and it is known that he wrote some 14 plays, of which only three remain. The influence of the Spanish dramatist Pedro Calderón de la Barca toward the end of the period is incontestable.

Lyric poetry was written profusely during the baroque period; a competition held about 1680 brought forth over 500 poems. Among poets of note were Luis de Sandoval y Zapata, Alonso Ramírez de Vargas, and Matías de Bocanegra (1612–1668). Sandoval and Ramírez were more Gongoristic in their metaphors; Bocanegra's style was sweeter, but less coloristic. His claim to fame is based on his *Canción a la vista de un desengaño* (c.1650), a sort of precursor of neoclassicism which breaks away from the two great baroque tendencies holding absolute sway over the literary production of the times, the pompous *culteranismo* and the deliberately ambiguous metaphors and puns of conceptism. Nor must one omit Friar Miguel de Guevara (c.1585–c.1646), who is credited with the sonnet *No me mueve mi Dios para quererte,* one of the best in the Spanish language.

But before all these must be placed the name of Juana Inés de la Cruz, born near Mexico City in 1648 (or perhaps, according to older documentation, in 1651). Precocious and intelligent, she was for a time at the viceroy's court; but later entered the Convent of San Jerónimo, where she died in 1695. She was a woman of great talent and very wide culture, the author of religious works, a musical treatise now lost, some religious

and some secular plays, like *Los empeños de una casa* and *El divino Narciso,* and a great number of poems, many of them first rate, especially *Primer sueño.* This poem, nearly 1,000 lines in length, deals with a broad and universal subject in a continuous succession of extremely lyrical baroque metaphors, and is a poetic interpretation of a dream—in the human body, in nature, in the cosmos—followed by the awakening and the return to life and to conscious being. Within the baroque style is a forerunner of modern literature based on the experiences of the subconscious. Such extensive writings place their author not only in the first rank in her time but among the best writers in the Spanish language.

Literary production shows a very definite decadence in every branch in the first half of the 18th century, reaching extremes of exaggeration, confusion, senselessness, and bad taste. The baroque had exhausted its possibilities; new trends were in the making. One of the effects was a drifting of intellectual interest mainly to the sciences, as far removed as possible from the exclusively literary activity of the previous period.

The most remarkable product of this new trend in New Spain was the writings of the group of Jesuits exiled from Spain and her colonies in 1767 by order of the king. They published their work in Italy, and although circumstances forced them to write in Italian or in Latin, as a group they caused the first awakening of the consciousness of Mexico, now fully distinguished from its Spanish origin. The most important were Francisco Xavier (or Javier) Clavijero, author of a comprehensive history of pre-Hispanic Mexico, *Storia antica del Messico* (Cesena 1780–1781); Rafael Landívar, author of *Rusticatio Mexicana* (Bologna 1782), in which he described the beauty of the Mexican countryside and customs; the historians Francisco Xavier Alegre and Andrés Cavo; and the aesthetician José Márquez.

Neoclassicism.—In ousting the baroque, neoclassicism gave rise to a type of formally correct lyric poetry, but showed a marked preference for minor themes and a certain weakening sweetness. Examples of this type of writing are found in the work of Father José Manuel Sartorio (1746–1828) and Friar Manuel Navarrete (1768–1809).

During the struggle for independence (1810–1821), as was to be expected, writers concentrated on the political conflict, and it is this trend that the scanty production of the times followed. The most important name was that of José Joaquín Fernández de Lizardi (1776–1827) who wrote many political works under the pseudonym El Pensador Mexicano (The Mexican Thinker). His novels *El Periquillo Sarniento, La Quijotita y su prima,* and *Don Catrín de la Fachenda,* in which he criticizes the customs of the times, are far more important to us nowadays. These were the first novels to be written in Spanish America. The picaresque *El Periquillo Sarniento* (1816) was translated into English by Katherine Anne Porter, as *The Itching Parrot,* in 1941.

The 19th Century.—Men of letters of the first few years of independent Mexico fall into two groups: neoclassicists and romanticists. Of note among the former were: Manuel Sánchez de Tagle (1782–1860), José María Heredia (1803–1839), Manuel Carpio (1791–1860), José Joaquín Pesado (1801–1861), and the playwright Manuel Eduardo de Gorostiza (1789–1851), who is best remembered for his plays *Contigo pan y cebolla, Indulgencia para todos,* and *Don Dieguito.*

Romanticism came to Mexico shortly after the country's independence, as a French influence. Young writers took to it with devoted zeal. Of these were José Ignacio Rodríguez Galván (1812–1842), a prolific but inaccurate poet, author of two romantic dramas, *El privado del virrey* and *Muñoz, visitador de México;* and Fernando Calderón (1809–1845), also a poet, and author of the plays *Herman, o la vuelta del cruzado* and *Ana Bolena,* among others, as well as a play in which he criticizes the customs of the times, *A ninguna de las tres.* Among the early romantic novelists were Florencio María del Castillo (1828–1863), Juan Díaz Covarrubias (1837–1859), and Justo Sierra O'Reilly (1814–1861). The last leaned toward the historical novel, as did Eligio Ancona (1830–1893), and Vicente Riva Palacio (1832–1896). Manuel Payno (1870–1894) preferred the novel of adventure.

About the middle of the century there was an almost uninterrupted 20 years of wars and civil wars (1847–1867)—including the invasion from the United States, which wrested from the nation half its territory, the Liberal reform movement, which succeeded in breaking the power of the Roman Catholic Church, and the French invasion and the country's struggle against Maximilian's empire. All these factors encouraged the development of new literary forms: oratory, political essays, and history. Prominent in these fields were Francisco Zarco (1829–1869), Ignacio Ramírez (1818–1879), Clemente de Jesús Munguía (1810–1868), and others. José María Luis Mora (1794–1850), Lucas Alamán (1792–1853) and Manuel Orozco y Berra (1818–1881) dealt with political history.

When peace came, a second and last romantic flowering took place, with the poets Manuel Acuña (1849–1873), Manuel M. Flores (1840–1885), Agustín F. Cuenca (1850–1884); the playwright José Peón Contreras (1843–1907); and the novelist Pedro Castera (1838–1906).

The trend of the last genre was toward the novel of manners, with such authors as Guillermo Prieto (1818–1897) and José T. de Cuéllar (1830–1894); but it soon drifted toward realism, whose first adherent was Luis G. Inclán (1846–1875), followed by Ignacio Altamirano (1834–1893), Rafael Delgado (1853–1914), José López Portillo y Rojas (1850–1923), and Federico Gamboa (1864–1939). The novel of the turn of the century was inspired by the French and Spanish realistic novel, but by its very nature—because of its method, which was based on the observation of surrounding reality, in taking note and making use of it—it gave rise to novels which differed more and more consciously from their European models and which took on more of the country, the people, and the color of Mexico; in other words, the true Mexican novel was being created.

Poetry, which has always been a most important literary activity in Mexico, as well as in the whole of Spanish America, also experienced a considerable change, influenced by French Parnassianism and symbolism, in those years of transition between romanticism and modernism.

Histories of Spanish American literature also mention the premodernistic poets of the transition period; first place always being given to Manuel Gutiérrez Nájera (1859–1895), who was

also an extremely fine and nimble prose writer.

The triumph of modernism dates from about 1890, and the movement lasted for more than 20 years. The poets of modernism were Efrén Rebolledo (1877–1929), erotic and curt; José Juan Tablada (1871–1945), who made use of Japanese exoticism, and became a brilliant newspaperman; and Amado Nervo (1870–1919), who started from modernism and went on to achieve a more personal style. The latter achieved international renown in the Spanish-speaking world and great honors were bestowed on him at his death.

Though modernism was predominant, there were also other types of poets. Manuel José Othón (1858–1906) was classical by education and style. He was perhaps the poet who wrote best about the Mexican landscape. Salvador Díaz Mirón (1853–1928) sought perfection in form, and left a relatively small but magnificent production. Luis G. Urbina (1868–1934), always faithful to romanticism, was also a good critic and a fine prose writer.

The names of a few humanists must be added, men of profound classical culture, translators of the Greek and Latin classics and themselves careful writers in their own tongue, though often writing in Latin. Among these are Ignacio Montes de Oca y Obregón (1890–1921), Joaquín Arcadio Pagaza (1839–1919), Federico Escobedo (1874–1949), Francisco de P. Herrasti (1879–1940), the brothers Gabriel (1905–1949) and Alfonso (1909–) Méndez Plancarte, and Octaviano Valdés (1901–).

The 20th Century.—The Mexican Revolution of 1910 brought about a profound and all-embracing political and social upheaval. Mexican literature could not escape its impact, though its effect was felt late.

Novels.—The realistic novel mentioned above welcomed the warm echo of the revolution and a new branch sprang forth. This has been called by some "the novel of the revolution"; but the name is inexact, for much of the production did not, properly speaking, consist of novels, but rather of tales or anecdotes, sometimes memoirs, and short stories were abundantly written.

The general opinion is that the novel of the revolution began with *Los de abajo* (1916) of Mariano Azuela (1873–1952), author of some short biographies and a long series of novels, the best of which are *Malayerba, Sin amor,* and *La luciérnaga.* His best known work, *Los de abajo,* translated by Enrique Munguía as *The Underdogs* (1929), is no doubt a good novel, mainly because of its background and its characters. The structure leaves much to be desired, but this is a common occurrence in this author and, indeed, in most of the Mexican fiction writers of the present century. Generally speaking, Martín Luis Guzmán (1887–) is a better writer. Novelist, essayist, newspaperman, and politician, he is the author of a book of tales, *El águila y la serpiente* (1928), without doubt the best of its kind that has been written about the Mexican Revolution. This work was translated by Harriet de Onís as *The Eagle and the Serpent* (1930). There are other, not so successful, writers of this type of novel, such as José Rubén Romero (1890–1952), Rafael Muñoz (1899–), and others.

Some authors, like Ermilo Abreu Gómez (1895–), Francisco Monterde (1894–), and Julio Jiménez Rueda (1896–), followed a trend which started in the third decade of the century and which sought inspiration in the times of the viceroys; hence it was called *colonialismo.* The authors mentioned have written excellent short stories, novels, dramas, and works of criticism; but realizing the mistake of finding inspiration exclusively in dead forms, they made a timely departure from their original aims. Artemio de Valle-Arizpe (1888–) alone has kept up the error.

The appraisal of Mexican social problems and the revision of certain historical opinions in favor of the Indian, as against the Spanish, roots of Mexican culture—so-called *indigenismo*—inspired many of the more recent short story and novel writers, most of whom are enjoying the fullness of their creative powers. Among these should be mentioned: Andrés Henestrosa (1908–), José Mancisidor (1894–), Mauricio Magdaleno (1906–), José Revueltas (1914–), Alberto Quiroz (1909–), Efrén Hernández (1903–), and Agustín Yáñez (1904–).

Poetry.—This art, meanwhile, had been following varied paths. Shortly before the outbreak of the revolution, the more sensitive writers foresaw the exhaustion of modernism and the need for a poetic revival. Beginning in 1909, this revival was led by Enrique González Martínez (1871–1952), physician and diplomat, who throughout his long life created works of such importance as to place him in the lead in Mexican literature. Also very important is Ramón López Velarde (1881–1921). His contribution was to make a place in poetry for provincial and familiar things, in a language full of tender sensitivity and unexpected imagery.

A group of young writers conceived the idea, imperfectly understood by most people, of strengthening the bonds, at that time not very solid, between the literature of Mexico and that of other countries. They published a literary review, *Contemporáneos* (1928–1931), from which the group of its contributors was named. Their writings were usually accessible only to an intellectual minority, but usually kept to very high standards of achievement. They wrote a great deal of poetry, some prose fiction, and some drama. Of this group were Jaime Torres Bodet (1902–), Xavier Villaurrutia (1903–1950), the brothers José (1901–) and Celestino Gorostiza (1904–), Gilberto Owen (1905–1952), Jorge Cuesta (1903–1942), and Bernardo Ortiz de Montellano (1899–1949), among others.

Lyric poetry has always been favored by women writers in Mexico. The number of women poets has grown and their standards have improved considerably in modern times. Important work has been done since about 1930 by Concha Urquiza, Margarita Michelena, and Guadalupe Amor.

Drama.—The first of the literary genres to be cultivated in Mexico, from the days immediately following the conquest in the 16th century, entered a period of decadence after the baroque era. The decline continued during the following two centuries, and with ever-quickening tempo after independence. After the turn of the century, psychological drama replaced moral plays in the European theater; the romantic theater was followed by realism, under the strong influence of the Scandinavians through the Théâtre Libre of André Antoine in Paris. Whatever drama was written in those days in Mexico has only an historical interest for us. The only

name worth mentioning is that of Marcelino Dávalos (1871–1923), a facile poet and author of several well-constructed plays; but their subjects were romantic and their characters distorted by an excessively realistic point of view.

Before the revolution every theater was kept busy showing various kinds of the Spanish type of operetta called zarzuelas. The revolution, however, caused a very specific change and innovation, the Mexican review, in which criticism and politics carried the day. Unfortunately, it never reached a really artistic or literary level.

Tentative efforts made after 1920 later turned into an open and decided attempt at creating a Mexican theater movement, which would blaze a trail for the artistic expression of the country. José Joaquín Gamboa (1878–1931) and Víctor Manuel Díez Barroso (1890–1936) are the outstanding writers of those years. Taken together, their works clearly reflect the evolution of the theater, similar to that of Europe, from the naturalistic drama to the drama subsequent to the influence of Henrik Ibsen. But it is perhaps more important to point out the struggle toward the achievement of a national drama movement, which was being conducted both by individuals and by experimental groups like the Comedia Mexicana, the Teatro de Ulises, and the Teatro de Orientación. These struggled on, partially encouraged by insufficient and sporadic government grants. It has been only comparatively recently, really since 1946, that the government has seriously undertaken to encourage authors and actors working exclusively in Mexican media. It is fitting to mention among contemporary authors Xavier Villaurrutia (1903–1950), and above all Rodolfo Usigli (1905–), author of first-rate plays like *Otra primavera, Media tono,* and *El gesticulador.* Usigli's best qualities are in the precision and psychological vigor of his characters, in the construction of his plays, and in the powerful social and political criticism which they contain.

Essays.—Very few essays have been written by Mexican authors. They are first found with the introduction of modernism, mixed and confused with newspaper articles and critical reviews. This form later gained new importance with the impulse given to it by the group that was called Ateneo de la Juventud (Athenaeum of Youth), later renamed Ateneo de México, toward 1910. It was a splendid group of people, highly productive under the guidance of the eminent Santo Dominican intellectual Pedro Henríquez Ureña. Of this group were the essayists, and also philosophers, Antonio Caso (1883–1946), José Vasconcelos (1882–), Julio Torri (1889–), and Alfonso Reyes (1889–). Essay writing was also taken up later by Xavier Villaurrutia, Andrés Iduarte (1905–), Octavio Paz (1914–), and various others; but above them all stands Alfonso Reyes, a native of Monterrey, who apart from being a diplomat for 30 years, has successfully written short stories and dramas, and has done extensive research and literary criticism. His works are legion. A few of the most important are: *Cuestiones estéticas* (1911); *Visión de Anáhuac* (1917); *Huellas* (poetry, 1922); *Ifigenia cruel* (poetry, 1924); *Capítulos de literatura española* (1939); *La crítica en la edad ateniense* (1941); *La experiencia literaria* (1942); *El deslinde* (1944); and his version of the *Iliad* (1952). Alfonso Reyes is, without a doubt, the most important, of greater literary knowledge, and the most devoted and most careful writer that Mexico has ever produced. See also LATIN AMERICA—*Spanish American Literature.*

Professor of Literature, Universidad Nacional de México; Researcher, Instituto de Investigaciones Estéticas.

20. MUSIC. Pre-Hispanic.—Of the music of prehistoric Mexico, only instruments (clay whistles), found under the lava that forms the Pedregal de San Ángel on the southern outskirts of the capital, have been preserved.

In the 4th to 10th centuries the Maya culture flourished in southern Mexico, Guatemala, and western Honduras. The large monuments of the region—temples, palaces, and pyramids—as well as their reliefs and statues, are proofs of the refinement attained by Maya culture. After a short period of decadence this culture sprang up again on the Yucatán Peninsula in the 10th century.

In reality very little is known concerning the customs of the Mayas. With regard to music, we know that they had a singer and a principal director in charge of the instruments that accompanied the dances with which they celebrated their religious festivals. These instruments, which are well known through the frescoes discovered in 1946 at Bonampak, Chiapas, were: conchs used as horns, of raucous sound; large trumpets, probably of wood; turtle shells struck with the horns of deer; wooden oboes; whistles and flutes of cane and deer bones; drums; and the *tunkul,* which the Aztecs called the *teponaztli.* Conchs and the *tunkul* served particularly to call the people to the temples.

The *tunkul,* or two-tone slit drum, made from the trunk or limb of a hardwood tree such as the sapodilla, is an instrument without equal in the ancient world. It consists of a wooden cylinder placed on its side, generally from two to three feet long and about a foot in diameter, which has been hollowed out through the base. The latter is left open, except for a "pillow" at each end to support the instrument. In the center of the upper part are two small tongues produced by two parallel longitudinal slits connected by another, in the form of an H. These tongues are struck with rubber-tipped sticks and produce the two tones, the musical interval varying with such factors as the length and mass of each tongue.

Music and dance played a very important role in Maya worship and in that of the Mixtecs and Zapotecs of Oaxaca and the Tarascans of Michoacán.

The Texcocans, who in the reign of Nezahualcoyotl (15th century) were the most civilized of the peoples in the Nahua confederation, had schools and fraternities similar to academies for the cultivation of poetry and music.

The musical life of the Aztecs has come to us in more detail. The wealthy class had its own group of singers, and generally composers

also. The great lords and the temples had for their exclusive service chanters, or composers of songs. In a like manner, the king had his musicians, perhaps poets also, who extolled in their songs the warlike deeds of the king, his lineage, and his great wealth.

In each of the 18 months of the Aztec year there was at least one important celebration, for each of which the dances, songs, and the dress were distinct. In the large festivals, in which there were up to 8,000 dancers, the first two or three circles of people were formed by the older lords and priests; the others, after leaving a space for the jesters who rambled about performing as buffoons, were formed by the youths. The Aztecs, however, danced as much in private festivals as in public ceremonies.

Dance and song were carefully taught not only in the *calmecac,* where the sons of the nobles were educated, but also in the great temple, where the young girls of the noblest houses lived, and in the *telpochcalli,* where the plebeian youths were educated.

The sounding of the alarm in the city of Tenochtitlan was given with the terrible *huehuetl* of the great temple. This was a "drum" about three feet high and 1.5 feet in diameter, made of a hollowed tree trunk, over the top of which was stretched a deer or jaguar skin, while the bottom was supported by feet. It was beaten with the hands, fingers, or sticks as various usages required.

The instrument of warfare, to communicate orders, was the conch, of frightful sound. The signal for combat was communicated by *teponaztlis* which the chiefs carried at their sides, that of the supreme chief being made of gold.

Colonial.—Together with the rest of the culture of the Indians, their music fell victim to the implacable persecution of the friars. To the peremptory prohibitions placed on the music and dances of the Indians, one must add, as the cause of the absolute extermination of Indian music, the early opening of schools of religious music in the churches and convents. In fact, scarcely had the final capture of Tenochtitlan (now Mexico City) taken place, when Fray Pedro de Gante in 1524 founded the first music school, at Texcoco, to teach the Indians the musical essentials for the religious services, and the making of instruments. This school was moved to Mexico City in 1527, and in a short time there was scarcely a church or convent without a music school, or a town without Indian singers. Their teachers found great talent for music and declared that "they advance in months what in Spain the Spaniards do in two years."

Thus, in the hands of the conquerors, ended the great Indian music—the music that had been composed for the Indian lords and that which had accompanied the temple ceremonies. Only rural and pastoral music remained, defended by the jungle or the rugged mountains. Its pure remains are now to be found principally among the Seri Indians of Tiburón Island, Sonora; the Yaqui of southern Sonora; the Tarahumara of Chihuahua; the Huichol of Nayarit; the Cora of Jalisco; the Lacandon of Chiapas; and the Maya of the Yucatán Peninsula.

Very little of the dazzling sparkle of the Renaissance came to New Spain. Musical life in the colony remained as if in a state of sleep. In the theaters, there were only frivolous little songs and immodest little dances, done by assembled companies of castoffs from Spain. The devout, however, had the occasion to hear in their vespers, their matins, their tierces, and solemn masses something of what the great mystic composers of Europe produced.

Four colonial composers are worthy of note because of the high quality of their works. José de Lienas, whose style shows that he lived in the second half of the 16th century, was an able polyphonic composer. Hernando (or Fernando) Franco reached Mexico City in 1575 and died in 1585. He was choirmaster of the cathedral and his compositions consist of religious works in the best style of the Roman school. Antonio de Salazar is known to have been choirmaster in the cathedral between 1685 and 1715. His works are religious: motets, masses, hymns, and a great number of *villancicos.* José María Aldana, who died in 1810, was a violinist in the cathedral and the composer of numerous religious works, including a *Te Deum* and a Mass in D Major.

The people showed an extraordinary musical activity. *Jarabes, sones,* and *huapangos* of a thousand suggestive names are touched upon in the reports of the epoch—and the archives of the Inquisition. Everywhere they were spoken of as diabolical inventions; on all sides there arose a clamor which called these popular songs shameful, indecent, and sinful.

The folk music of Mexico is the result of three currents: the Indian, the European, and that of the Negroes brought as slaves by the conquerors. The *corrido,* a narrative ballad which derives from the Spanish *romance,* and the *canción* are two song types found all over Mexico. The most characteristic dance forms, generally accompanied by singing, are: the *son,* found almost everywhere; the *chilena* of Guerrero; the *jarana* of the Yucatán Peninsula; the *huapango* of the Gulf coast, principally in Veracruz and Tamaulipas; and the *jarabe,* of which the most popular types are those of Jalisco and Michoacán and the *jarabe largo* of Veracruz. *Jarabes* are suites of *sones* danced by couples without embracing. The three types differ from one another in the *sones* which make them up and in the steps by which they are danced.

The 19th Century.—The musical geography of the country was defined during this century. The *jarabe* divided into the Jalisco and Michoacán types; the *canción* of the Bajío and that of the Central Plateau established a style full of Italian influence; African influence fastened itself along the Gulf coast; and the Viennese waltz found shelter among the islanders of Lake Pátzcuaro in Michoacán.

The 19th century, with the independence of Mexico (1821), also brought the first effective importation to the musical life of the country. For the first time, musicians of merit arrived and Mexico heard Italian music sung by large opera companies.

Three main impulses initiated the musical movement in the country: the founding in Mexico City of the Sociedad Filarmónica by Mariano Elizaga in 1825, and of the Gran Sociedad Filarmónica by José Antonio Gómez in 1839, and the establishment of the Sociedad Filarmónica Mexicana by Agustín Caballero in 1866. From these three were born the Conservatorio Nacional (founded 1877), symphonic and solo concerts, and choral organizations and concerts.

Ricardo Castro (1864–1907) and Julio Ituarte (1845–1905) composed fantasies dealing with Mexican themes. Castro's principal works are a piano

concerto and the operas *La Leyenda de Rudel* and *Atzimba.* Aniceto Ortega (1823–1875) composed the opera *Guatimotzin* (another name for Cuauhtemoc, the last Aztec emperor), which was presented in 1871 and had an extraordinary success. Two other composers, Felipe Villanueva (1862–1893) and Juventino Rosas (1868–1894), succeeded in gaining universal renown with two waltzes: Villanueva with the *Vals Poético;* Rosas with *Sobre las Olas.* Villanueva was also the composer of the opera *Keofar,* presented in 1893.

The first artist to make the name of Mexico known to the European continent was Angela Peralta (1854–1883), a soprano with a prodigious voice and great talent that aroused tremendous enthusiasm during a tour of the principal cities of Italy and France.

At the end of the 19th century, Carlos J. Meneses (1863–1929) started the symphonic movement in Mexico, formed a true symphonic orchestra, and made known the most important works of that class of music.

Modern.—Music in the 20th century follows the paths of nationalism, timidly aimed at by Castro and Ituarte. The latest European currents are represented: the German by the violinist and composer Julián Carrillo (1875–), author of numerous treatises and of the theory of Sound 13, based on the subdivision of the semitone; and the French by Gustavo E. Campa (1863–1934). The latter's most important work is the opera *El Rey Poeta,* based on the life of Nezahualcoyotl, the 15th century poet-king of Texcoco.

During the Revolution of 1910 the great composer and pianist Manuel M. Ponce (1882–1948) brought the music of the people into aristocratic salons with his stylizations of Mexican folk songs. After the revolution had ended, the interest of Mexican musicians and musicographers was oriented toward folk music, led by Ponce. The latter, José Rolón (1883–1945), Candelario Huizar (1888–), the pianist and composer Silvestre Revueltas (1899–1940), and Carlos Chávez (1899–) began to produce works which used the essentials of Indian or mestizo music, according to the personal inclinations of each composer, and thus a national style continued to form. Rolón is particularly known for his heroic poem *Cuauhtemoc* (1929), the symphonic suite *Zapotlán* (1941), and a concerto for piano and orchestra (1942); Huizar, for several symphonies, and the symphonic poems *Imágenes* (1929), *Pueblerinas* (1931), and *Surco* (1935); Revueltas, one of Mexico's most gifted composers, for the orchestral works *Cuauhnahuac* (1933), *Janitzio* (1933), and *Sensemayá* (for orchestra and chorus; 1938), and music for the film *Redes* (1935); Chávez, for his ballets *El Fuego Nuevo* (1921); *Los Cuatro Soles* (1926), and *H.P.* (for "Horsepower," 1926–1927), and the symphonies *Sinfonía de Antígona* (1933) and *Sinfonía India* (1936).

The principal works of Luis Sandi (1905–) are *Norte* and *Theme and Variations* for orchestra; *El Venado* for Mexican orchestra, performed in New York in 1940 under the title of *Yaqui Music;* the opera *Carlota,* presented in 1948; the ballet *Bonampak,* presented in 1951; as well as a string quartet, and *Troyanas* for chorus and small orchestra. With the exceptions of the last two compositions and *Carlota,* the nationalistic style predominates in Sandi's works.

The profound difference between the 20th century and previous periods is that while there were Mexican composers before the 20th century, they produced Italian, French, and German music; now Mexican musicians produce music which is increasingly Mexican in character.

During the second quarter of the century there was realized a transformation that tended to modernize the musical language of the composers and the taste of the public. Carlos Chávez, first as director (1928–1934) of the Conservatorio Nacional, and later as director of the Orquesta Sinfónica de México, besides being a notable composer, was the soul of this movement.

Among the Mexican artists most famous in Mexico are: the singers Fanny Anitúa, José Mojica, Irma González, Oralia Domínguez, and Carlos Puig; and the pianists Angélica Morales and Miguel García Mora.

Mexico has eight orchestras: the National, the University, the Mexico City, and the Chamber Orchestra of Mexico, all in the capital, and the orchestras of Jalapa, Mérida, Guadalajara, and Guanajuato; as well as five choruses: the Madrigalistas, the Conservatory Chorus, the Boys Chorus of the Conservatory, the Boys Chorus of Morelia, and the Male Chorus of the Escuela Nocturna de Música; and also the National Opera Company.

The most distinguished composers of the middle of the 20th century, in addition to those previously mentioned are: Daniel Ayala Pérez (1908–), Miguel Bernal Jiménez (1910–), Salvador Contreras (1912–), Blas Galindo (1910–), and Pablo Moncayo (1912–), who may be catalogued as belonging to the nationalistic school; Eduardo Hernández Moncada (1899–), Rodolfo Halffter (1900–), Jesús Bal y Gay (1905–), Luis Herrera de la Fuente (1916–), and Carlos Jiménez Mabarak (1916–), who follow more or less advanced modern currents; and José Francisco Vázquez (1893–), whose style may be called postromantic, as may that of Miguel Bernal Jiménez.

Useful material may also be found in the *Anales* (*Annals*) of the Instituto de Investigaciones Estéticas and the *Anuario* (*Annual*) of the Sociedad Folklórica de México.

Luis Sandi,
Composer; Director, Madrigalistas Chorus; Chief, School Music Section, Instituto Nacional de Bellas Artes; Director General, Juventudes Musicales de México.

21. MOTION PICTURES. The first Mexican cinematographic activities were of a documentary nature. Photographers of the turn of the century, such as Salvador Toscano (1872–1947), have left us a wealth of documentary films on the Porfirio Díaz regime and the Mexican Revolution of 1910. *El Grito de Dolores* (1910), based on the stirring appeal to revolt from Spain made by Father Miguel Hidalgo in 1810, was the first motion picture to be filmed in Mexico. Natives of the region were employed to represent the patriots and Spanish soldiers. During the actual filming

they became so imbued with their roles that near bloodshed occurred.

In the year 1916, one of the bloodiest of the revolution, the first filming company, México Lux, was founded. Sporadic and ill-directed efforts to create other filming companies had met with little success and it was not until World War I cut off the supply of European films that the Mexican film industry began to produce on a fairly healthy basis. Various other companies were founded during the war years, the most prominent being Azteca Films owned by Germán Camus, Productora Quetzal owned by Jorge Stahl, and Bandera Films. The films which received the widest acclaim and popularity abroad were *Santa* (1917), a melodrama taken from Federico Gamboa's Mexican novel; *Tabaré* (1917), an Indian story; and *El Automóvil Gris* (1919), a cops-and-robbers thriller.

With the war over, Hollywood production created a crisis in the infant motion picture industry of Mexico. This crisis was further aggravated by the introduction of the "talkies." However, this proved to be a blessing in disguise, since the Mexican movie-going public began to insist on films with dialogue spoken in their own language.

During the 1930's a vast source of potential customers was opened up among rural and village inhabitants. Many well-known cinema personalities embarked on their film careers at this time. The director Emilio Fernández (1909–); Gabriel Figueroa (1907–), cameraman of world-wide fame; the brothers Andrés (1900–), Fernando (1900–), Domingo (1901–), and Julián (1910–) Soler, actors; Jorge Negrete (1911–), Mexican singing cowboy; Andrea Palma, actress; Arturo de Córdova (1908–), actor; and Mario Moreno (1911–), known as Cantinflas, mimic and comic, imitator of the likable Mexican "low-lifer" and idol of the Mexican movie-going public, all got their start in the film industry during the 1930's.

Many Spanish-speaking actors in Hollywood were lured south of the border by the nascent Mexican filming industry. Such well-known artists as Virginia Fabregas (1880–) and José Mojica (1895–), the singer who later gave up fame and fortune to join the Franciscan Order, became leading figures in Mexican films. The greatest film presentation of this period was the cowboy musical *Allá en el Rancho Grande* (1936), the vehicle that carried Tito Guizar to success and popularity as a matinee idol. Artistically, *La Noche de los Mayas*, portraying an Indian legend, produced in 1939, was perhaps the best film of this era.

Since the Mexican film industry caters primarily to a national market, a great many of its films draw on historical or folklore themes. Mexican producers seem to have mastered this type of medium. Such fine films as *María Candelaria* (1943), dealing with the clash of urban and rural cultures in a village near Mexico City, with Dolores del Río in the stellar role, and *Río Escondido* (1947), which portrayed the repercussions arising from the introduction of a school in a Mexican village and had the lovely María Félix (1914–) as the feature star, are proofs of the excellence and high artistic quality of their productions. On universal themes, they have produced works which have received world acclaim, such as *Doña Bárbara* (1943), starring María Félix. This was based on the Venezuelan novel by Rómulo Gallegos.

With minor setbacks, the Mexican film industry has continued to expand. In 1952 Mexico occupied first place among the Spanish-speaking countries as a producer of films, followed by Argentina and Spain. Excluding the USSR, Mexico ranked fourth in world ratings as a producer of motion pictures.

FILM PRODUCTION

Year	Films Produced	Reviewed	Average Filming Cost (pesos)
1931	2	0	40,000
1932	8	4	45,000
1933	18	12	50,000
1934	25	25	55,000
1935	21	26	58,000
1936	22	18	75,000
1937	36	32	81,000
1938	50	43	128,000
1939	37	37	135,000
1940	27	32	75,000
1941	46	28	156,000
1942	49	47	278,000
1943	67	57	350,000
1944	78	63	580,000
1945	79	63	648,000
1946	74	79	579,000
1947	54	60	450,000
1948	82	72	400,000
1949	109	101	450,000
1950	125	104	480,000
1951	102	112	540,000
1952	94	99	600,000

The origin of films exhibited in Mexico is shown in the following table:

Country of Origin	1949	1950	1951	1952
United States	250	228	243	274
Mexico	101	104	112	99
France	20	23	18	22
Great Britain	17	7	3	19
Spain	20	13	16	15
Italy	6	13	10	10
Argentina	8	4	6	3

An insignificant number of Portuguese, Chilean, Russian, and Japanese films were also exhibited during these years.

The Banco Nacional Cinematográfico, a public bank founded in 1941 to assist in developing the Mexican film industry by furnishing 50 per cent of the capital, which financed 30 per cent of the films produced in 1946, classified film production as the fourth major industry in the country in the latter year. By 1951 it had declined to seventh place in importance. In 1951 there were approximately 26,000 people working in the film business, with a total investment of 618 million pesos. Approximately 50 studios are owned by Churubusco, Azteca, Clasa, San Angel Inn, and Tepeyac studios, all of which are located near Mexico City. Tepeyac boasts the largest studio in the world.

There were 130 motion picture theaters in Mexico City and 2,021 others scattered throughout the country in 1952. Mexico City theaters during the fiscal year 1950–1951 grossed 14,065,434.85 pesos and paid 2,165,013 pesos in taxes to the government.

According to data furnished by the *Anuario Estadístico*, in 1934, 70.1 per cent of all spectators attended the cinema, 22.5 per cent attended the legitimate theater, 2.4 per cent attended sports events, and 1.7 per cent attended bullfights and cockfights. In 1947 cinema attendance had increased to 92.4 per cent, while theater attendance dropped to 1.7 per cent, with sports attendance and attendance at bullfighting and cockfighting events remaining unchanged.

In world competition, Mexican films have consistently placed in the high rankings. In 1946 at

the Cannes Film Festival the photographer Gabriel Figueroa won acclaim with *María Candelaria;* in 1947 at Brussels he again triumphed with *Enamorada* (1946), a drama of the revolution. In the same year he was awarded the International Prize at Venice for *La Perla* (1945), a drama dealing with fishermen; Pedro Armendáriz (1912–) and María Elena Márquez were given trophies for their acting in this film. Figueroa also won a prize at Locarno for *La Perla* in 1947. In the next year at Madrid Figueroa won the photography prize for *Río Escondido,* while Emilio Fernández won acclaim for his direction. Figueroa and Fernández duplicated this feat at Prague in 1948. In 1950 at Madrid the first prize went to *El Dolor de los Hijos* (1950), a melodrama. Once again Figueroa's photography won a prize, for the rural drama *Pueblerina* (1948). At Venice in 1950 Figueroa gained further laurels for *La Malquerida* (1949), based on the drama by the Spaniard Jacinto Benavente. In the next year at Cannes, the Mexican-Spanish director Luis Buñuel won acclaim for *Los Olvidados* (1950), exhibited in the United States as *The Young and the Damned,* a film dealing with Mexican adolescents. In 1953 at Cannes a special prize was awarded to Emilio Fernández for *La Red,* a drama of the Pacific coast of Mexico, involving two men and a woman and the resulting play of passions.

Following an old Hollywood custom, the Academia de Artes y Ciencias Cinematográficas (founded in 1948) presents an "Ariel," which is similar to the Hollywood "Oscar," to the best director, the best photographer, and to the best actors of the year.

Journalist; Ethnologist, Escuela Nacional de Antropología.

22. SCIENCE AND SCIENTIFIC INSTITUTIONS. Astronomy.—There are several centers devoted to astronomy (astrophysics in particular) and related fields, such as the Tonanzintla Astrophysical Observatory, established in 1942, in the State of Puebla, where a group of workers is concentrating on the investigation of novae, spectrography of stars, and so forth, and the Observatorio Astronómico Nacional (National Astronomical Observatory), founded in 1878, in Tacubaya, near Mexico City, which for many years has been in charge of the Mexican portion of the chart of the sky. Smaller observatories at state universities and colleges carry on descriptive astronomical work. An astronomical society (Sociedad Astronómica de México) has existed in Mexico City since 1902. It maintains a small observatory for amateur study.

Geography and Geodesy.—Geodetic and geographic work is under the care of a federal government agency, the Dirección General de Geografía, Meteorología e Hidrografía, also located in Tacubaya, Federal District. Unfortunately, lack of sufficient appropriations has somewhat hampered its work, and the old charts to the scales of 1:100,000 and 1:500,000 were never finished, or contain a considerable number of blanks where modern facilities for geographic work could be employed, or more study should be done. However, very useful topographic charts for most of the states have been published, as well as other charts for different purposes. The army has a cartographic office, in charge of the new 1:100,000 map of Mexico, using air navigation charts and other data, of which 26 sheets had appeared by the beginning of 1953. The state government of Jalisco also maintains a geographic institute at Guadalajara.

The Sociedad Mexicana de Geografía y Estadística (Mexican Society of Geography and Statistics), established in 1833, and its branches in most states, have large collections of maps of all kinds, as well as much other data useful to geographers, meteorologists, and cartographers. A bulletin of a specialized nature has been published by the society at more or less regular intervals since 1839.

Geology.—The geological sciences have been taken over from the old Instituto de Geología in Mexico City (founded in 1891 and now a division of the Universidad Nacional de México) by several organizations, official and semiofficial. Large collections of rocks and fossils are kept for research at the institute, and there is a large library and other facilities for study. Its publications now reach a large number, covering all fields of geology. Structural and historical geological studies are carried out on a large scale by the government petroleum agency, Petróleos Mexicanos, geohydrological work is done by the Secretaría de Recursos Hidráulicos, a department of the federal government, and mining geological investigations are conducted by the Instituto Nacional para el Estudio de los Recursos Minerales (National Institute for the Study of Mineral Resources) established in Mexico City in 1944; all of these extend their studies to the whole country. The Bank of Mexico, through its Geological Department, has concentrated on coal and iron resources. All these agencies occasionally publish the results of their work. There is also the Sociedad Geológica Mexicana (Mexican Geological Society), in the capital, founded in 1904, and the Asociación Mexicana de Geólogos Petroleros (Mexican Association of Petroleum Geologists), organized in 1949, both with publications in the form of bulletins and maps.

Meteorology.—A new center for meteorological studies in the Gulf of Mexico was established in the port of Veracruz in 1950, in connection with the Servicio Meteorológico Mexicano (Mexican Meteorological Service), at Tacubaya, founded in 1877 by President Porfirio Díaz. Some states, like Jalisco and Yucatán, also have local networks of meteorological stations for weather forecasting. In Mexico City a meteorological chart is published daily, with forecasts for the next 24 hours in the whole country, and also a meteorological bulletin once a month, with summaries of national, state, and regional observations. The Sociedad Mexicana de Geografía y Estadística, mentioned under *Geography and Geodesy,* is also active in this field.

Physics and Chemistry.—These are the least developed branches of scientific research in Mexico, although many theoretical mathematical studies by Mexican workers on several aspects of both sciences have received international recognition. There is a Sociedad Mexicana de Física (Mexican Physics Society), founded in 1951, in the capital, with a bimonthly bulletin, and the Universidad Nacional maintains an institute in each of the corresponding fields. A small laboratory for nuclear research was established on the university campus in Mexico City in 1951. The new technological institutes in different states will undoubtedly contribute to the development of new studies. As re-

gards chemistry in particular, except for practical problems of an industrial nature, very little work of an original character has been done. Technical education and organizations are entirely professional.

Biology.—This is the best-represented field of scientific study, both in the pure and in the applied aspects. A long tradition of interest in plants and animals, coming down from pre-Hispanic days, has brought about a continuity in their investigation which other scientific studies have not enjoyed in the past. This interest in living beings includes native human populations, which offer a rich array of physical and cultural traits of great attraction to research (see section on *Anthropology*). The Sociedad Mexicana de Historia Natural (Mexican Natural History Society), in the capital, founded in 1868, embraces all fields of biological studies and publishes a well-known review. The Mexican societies of Hydrobiology (Hidrobiología) and Entomology (Entomología) organized in Mexico City in 1950 may also be mentioned among scientific organizations in this field.

Botany.—Botanical investigation of a systematic nature is done at the Herbario Nacional (National Herbarium), founded in 1788 and since 1929 a department of the Instituto de Biología of the Universidad Nacional, and at the Instituto Botánico (Botanical Institute) established in 1948 at Tuxtla Gutiérrez, Chiapas. Agricultural botany is studied in the Mexico City office of the Rockefeller Foundation, and at several less important agencies, like the Instituto Técnico Agrícola (Technological Agricultural Institute) of the sisal growers association, founded in 1934 at Mérida, Yucatán. There is also a Department of Agronomy at the Instituto Tecnólogico y de Estudios Superiores in Monterrey. Obviously cereals receive more attention in most states than other crops, but here and there small laboratories carry on research on special problems, such as pest control in citrus plants, and the like.

Forest products are most important in northern and southern Mexico, and the lumber industry maintains an interest in the study of areas in Durango and Chihuahua, in northern Mexico, as well as in the tropical rain forests in Campeche, Yucatán, and Quintana Roo, in southern Mexico. Some enterprising firms have started a scientific survey of possibilities, in the charge of properly trained staffs. There are several learned societies whose members are interested, as professionals or amateurs, in forest plants problems, and most of these organizations publish bulletins, special papers, and semitechnical information.

There are some 50 national parks in different regions of the country, largely so declared on the basis of an idealistic acceptance of the necessity of conserving natural resources rather than on a scientific understanding of the realities of Mexico. Studies of some of these national parks, like the Izta-Popo National Park, close to Mexico City, where some of the most famous volcanoes of the country are located, have been published.

Zoology.—Zoological studies are conducted in the capital at the Universidad Nacional's Instituto de Biología (founded in 1929) which has a natural history museum, at the Escuela Nacional de Ciencias Biológicas (National School of Biological Sciences), founded in 1936 and now a division of the Instituto Politécnico Nacional, and at other institutions of lesser academic standing. There are also museums of natural history in some state capitals, like Tuxtla Gutiérrez, Guanajuato, and Guadalajara, and most colleges and universities maintain collections of local interest. Applied zoology is developing swiftly in fisheries, cattle raising, and other aspects. There is an Instituto de Pesquería del Pacífico (Institute of Pacific Fisheries), founded in 1947 at Guaymas, Sonora, a Comisión Federal para el Fomento de la Piscicultura Rural (Federal Commission for the Development of Rural Pisciculture), founded in 1949 in Mexico City, and various zootechnic laboratories in the states. For the Sociedad Mexicana de Historia Natural see the section on *Biology*.

Physiology and Medicine.—There are research laboratories in several professional schools and hospitals, such as the Instituto Nacional de Cardiología (National Cardiological Institute), founded in 1946, the Instituto de Salubridad y Enfermedades Tropicales (Health and Tropical Diseases Institute), founded in 1939, and the Instituto de Higiene (Institute of Hygiene), founded in 1904. The first two are in Mexico City; the last near by at Popotla. Most hospitals maintain laboratories for special studies, and there is a great number of medical publications of all kinds, as well as societies and other groups for pure and applied research.

The Academia Nacional de Medicina de México, founded in 1864, represents the highest institution of its kind in the republic, and is housed in the old building of the medical college of the Universidad Nacional. As soon as new buildings for this school are finished, the old quarters will be turned over to medical societies in Mexico City for the establishment of a medical museum and appropriate libraries of professional character.

Anthropology.—Anthropology is centered in the Escuela Nacional de Antropología e Historia (National School of Anthropology and History), founded in 1937, in the Museo Nacional de Antropología (National Museum of Anthropology) in Mexico City, and in other agencies in that city and the state capitals. Some state governments like those of Michoacán, Veracruz, and Yucatán, maintain anthropological departments. There is a Sociedad Mexicana de Antropología, founded in 1937, in the capital, which publishes an annual review, as well as other societies for special studies. The Instituto Indigenista Interamericano (Inter-American Indian Institute), organized in 1940 in Mexico City and supported by the governments of the American republics, has several publications. The Instituto Panamericano de Geografía e Historia, founded in 1929 at Tacubaya, Federal District, also publishes a well-known annual bulletin in the field of anthropological bibliography. Lastly, there is an Instituto Nacional Indigenista (National Indian Institute), established in Mexico City in 1948, for ethnographical investigation.

MANUEL MALDONADO-KOERDELL,
Professor of Paleontology, Instituto Politécnico Nacional and Escuela Nacional de Antropología e Historia; Paleontologist, Gerencia de Exploración, Petróleos Mexicanos.

23. PHILOSOPHY. Colonial Mexico.—The cultures existing in Mexico before its conquest (1521) by the Spaniards possessed cosmic myths and moral ideas which may be considered as elements of a philosophy in the sense of *Welt-* and *Lebensanschauung* (outlooks on the universe and life), although founded neither upon scientific nor indeed upon rational bases as a philosophy in the strict sense. A philosophy in this sense was introduced into Mexico by the Spaniards, and was stimulated mainly through the foundation of the

university, Real y Pontificia Universidad (now the Universidad Nacional) de México, in 1551, and other centers of culture similar to those in Spain whose activities were partially devoted to the teaching of philosophy and to the development of scholasticism. The Spanish Augustinian monk Fray Alonso de la Veracruz (1504–1584) may be considered the father of this discipline in Mexico. He was the first professor of philosophy in the university and the author of didactic works, one of which, the *Recognitio Summularum* (1554), was the first philosophical treatise printed in the Americas.

During its first decades the colony was influenced by intellectual movements, more or less related to a philosophy in the strict sense, such as Renaissance humanism, utopianism, and Erasmism. These movements inspired works of beneficent colonization such as that performed by Bishop Vasco de Quiroga (1470–1565) in Michoacán. During these same years the colony was engaged in juridical issues and in various philosophically slanted polemics which followed in the wake of the conquest, mainly through the intervention of Fray Bartolomé de las Casas (1474–1566), the most celebrated of these polemists. However, when these influences and polemics had died out or at least had tempered themselves, the history of philosophy in Mexico until the second half of the 18th century was confined almost exclusively to the formulation of scholastic thought, although the problems, methods, and doctrines of modern science and philosophy were active in the minds of certain exceptional personalities, among them Carlos de Sigüenza y Góngora (1645–1700), who wrote on a wide variety of subjects, and the poetess Juana Inés de la Cruz (1651–1695).

At the beginning of the second half of the 18th century, a group of young Jesuits, cognizant of European philosophy and science, initiated a reform which affected mainly the teaching of natural philosophy as performed by their order. This was the introduction in their teaching of experimental and exact modern science (so-called experimental philosophy). The Jesuits Francisco Javier Clavigero (or Clavijero; 1731–1787), Francisco Javier Alegre (1729–1788), and Diego José Abad (1727–1779) were the best-known members of this group, due to the works they published in Italy (although these were not of a philosophical nature) after the expulsion of the Jesuit Order from the dominions of the Spanish crown in 1767. This expulsion, however, did not check the success of the reform, because of the zealous activity of a brilliant group of men, of whom the principal ones were disciples of the Jesuits.

With the sanction given by the university to the *Elementa recentioris philosophiae* (1774) of Juan Benito Díaz de Gamarra, a priest of the Order of the Oratory, modern philosophy and science in Mexico achieved a significant victory under the banner of an eclecticism similar to that of Europe in the 17th and 18th centuries. This eclecticism had been diffused in Spain and her colonies as a doctrine extremely well suited to the introduction of modern science and philosophy. Father José Antonio de Alzate (1729–1799), in whose honor the present Mexican Academy of Sciences was named, and others, criticized and satirized traditional scholasticism, cultivated the exact, natural, and human sciences, particularly in their relation to Mexico, and championed the cause of the scientific disciplines, principally in the practical field.

In the fulfillment of their task, the members of this group utilized cultural newspapers, among which the most renowned was Alzate's own *Gazeta de Literatura*. The scientific expeditions of Spaniards and other men of different nationalities, including that of the illustrious Alexander von Humboldt (1769–1859), stimulated their work. The foundation of new cultural centers, among which that of the Real Seminario de Minería (Royal School of Mines), in 1792, deserves mention, helped them in their activities. Thus they created a new intellectual environment in which philosophy in the full and applied sense of the 18th century had the leading part. The intellectual career of Miguel Hidalgo before his *Grito de Dolores* (1810), which launched the movement against Spain, offers convincing evidence that this philosophical movement was a decisive forerunner of Mexican independence.

Independent Mexico.—During the struggle for the consolidation of a country which had declared its independence, the philosophical tradition born of the colonial period suffered intermittent crises. The frequent closing of the academic halls of the university gave eloquent testimony to its precarious defense against the political philosophy of liberalism, the most important of the new philosophies of this period, whose main exponent was the ideologist José María Luis Mora (1794–1850). The university was definitively closed in 1865, and the triumph of the Liberals under Benito Juárez established the doctrine of positivism as the official philosophy of the country under the direction of the physician Gabino Barreda (1818–1881), founder of the Escuela Nacional Preparatoria (National Preparatory School) in 1867. This institution was responsible for the education or at least the philosophical orientation of the Mexican leaders, some of whom were members of the group known as the *científicos* ("scientists"), who preached economic progress and guided the public life of their nation during the successive regimes of Gen. Porfirio Díaz until the Revolution of 1910. During the latter year the outstanding *científico,* Justo Sierra (1848–1912), realizing that a reconciliation of the national culture and the new foreign ideological orientations was imperative, succeeded in re-establishing the university and in restoring within its walls a measure of freedom in the teaching of philosophy.

Likewise in 1910 constructive efforts to the same worthy cause were contributed by the group known as the Ateneo de la Juventud, among whose illustrious members were José Vasconcelos (1882–) and Antonio Caso (1883–1946), the two great masters of philosophy of modern Mexico, and also Alfonso Reyes (1889–). The latter is one of the most eminent of Latin American intellectuals. His ideological essays make excursions into the domain of philosophy; his *El deslinde* (1944) completely masters the realm of philosophy of literature. Caso presents in the most personal of his philosophical works, *La existencia como economía, desinterés y caridad* (3d ed. 1943), a veritable Christian existentialism, although before that term became popular. Vasconcelos has developed in his voluminous *Metafísica* (1929), *Ética* (1931), *Estética* (1935), and his later equally extensive *Lógica Orgánica* (1945), a system which fuses various philosophical influences from Plotinus to Henri Bergson into a very personal neospiritualism culminating in mystical aestheticism.

Samuel Ramos (1897–), in his *El perfil del hombre y la cultura en México* (1934), emerges as

the main forerunner of the most interesting movement in the recent development of philosophical thought in Mexico, one which tends to elaborate a philosophy of the Mexican and his culture. This movement was initiated in 1945 by the Grupo Filosófico Hyperión led by Leopoldo Zea (1912–).

In the modern intellectual life of Mexico the principal directions of contemporary philosophy are well represented, chiefly: neo-Thomism, by Oswaldo Robles (1905–); neo-Kantianism, by Francisco Larroyo (1908–) and Guillermo Hector Rodríguez (1910–); the philosophy of values, by Eduardo García Máynez (1908–), active also in the field of juridical logic, and José Romano Muñoz (1890–); also phenomenology, existentialism, and historicism by some of those already named, as well as other Mexicans, and by a group of Spaniards in exile in Mexico since 1938. These latter are working principally in the exposition and critical interpretation of the last-mentioned philosophical trends and in the history of ideas in Spain and Mexico.

24. PREHISTORY AND PRE-HISPANIC HISTORY. Setting.—Mexico is a land of strong geographical contrasts, a fact which greatly influenced the development of native civilizations. The arid lands of the north, to the east of the Sierra Madre Occidental, offered few incentives for the establishment of farmers before the introduction of European technology. This zone was occupied in pre-Hispanic times by nomadic food gatherers, with a very scattered population and a simple culture. This also applies to Lower California. The alluvial plains of the northwest, along the coast of the Pacific Ocean and the Gulf of California, irrigated by the rivers flowing from the Sierra Madre Occidental, and the well-watered mountains themselves, are exceptions to this. These northwestern regions were occupied, at the time of the conquest, by farming peoples who formed a link between the civilized peoples to the south and the cultivators of the southwestern United States.

To the south of a line drawn roughly from the mouth of the Pánuco River, on the coast of the Gulf of Mexico in northern Veracruz, to the mouth of the Santiago River, in Nayarit on the Pacific coast, the Indians took advantage of environmental conditions more favorable to agriculture, and developed complex sedentary cultures. Within the area south of this line, including central and southern Mexico, Guatemala, British Honduras, and the western parts of Honduras and El Salvador, there are extremes of environment, ranging from tropical rain-forest lowlands, through semiarid savanna country and fertile semitropical and temperate intermountain valleys, to cool uplands. These strong contrasts of relief within small areas result in the proximity of very diverse life zones, which, being complementary from the viewpoint of natural resources, have stimulated trade and conquests. These interregional relationships contributed to the development of basically similar cultures all over this territory—notwithstanding differences in patterns of regional specialization—constituting the culture area named Meso-America by ethnologists. Some of the most advanced American Indian cultures, having reached the stage of urban civilization, flourished here.

Sources of Information.—A consistent picture of cultural development covering at most 3,000 years and ending with the Spanish conquest can be traced for only a few areas of central and southern Mexico. It is based mainly on the historical reconstruction made possible through interpretations of findings in archaeological excavations. Only for the last centuries of this period do we have information based on reliable native historical sources.

These Indian sources could be classified in three groups, as follows:

(1) Native history preserved in the original form of folded books of picture writing. Due to the pictorial character of Indian writing these books were only summaries, consisting mainly of personal names, place names, and dates, with indications of the birth, marriage, and death of the personages, conquests, and so forth. The details were filled in by an oral tradition transmitted in the form of epics. Some of these epic poems have been preserved transcribed in the histories of group 2. Only a few of these books have survived the accidents of conquests, systematic destruction by overzealous friars and priests, or the ravages of time. On the basis of a group of picture-writing books known to have been made in the northern Oaxaca-southern Puebla region, Alfonso Caso was able to compile a list of Mixtec royal genealogies, going back to 692 A.D. according to his assertion. A preliminary account of this discovery was published in Caso's "El mapa de Teozacoalco," *Cuadernos Americanos* (Mexico City, September–October 1949).

(2) Histories written down (from formal oral tradition, or as transcriptions and interpretations of picture writing) after the Spanish conquest, in the Indian languages with the Latin script, or in Spanish. Quite a few of these refer to central Mexico, but the information they provide does not go back beyond the Toltec period (c.900 A.D.–c.1200). To this group belongs the *Relación de Michoacán*, which includes data for only the last two centuries before the Spanish conquest, and also the several *Books of Chilam Balam* of Yucatán. These books include historical data going back to the 5th century A.D., but only from the 10th century onward can we derive a consistent historical picture.

(3) Interesting historical information is found scattered in the answers to inquiries made by Spanish officials in the first decades of the colonial regime (particularly in the *Relaciones Geográficas*, 1579–1582), in petitions of the Indians to the Spanish authorities, and in other sources. These are valuable in that they reflect personal memories and what the people remembered as being historically important. They represent the limited local version of events, which can be compared with official history. Of course, the data provided by sources of this type cover only the last decades before the Spanish conquest.

The deciphered inscriptions of the so-called Long Count system of the ancient Maya give us a chronological framework for the greatest part of the first millennium of our era. However, it must be noted that the correspondence between

Maya Long Count dates and our calendar has not been securely established. Several different correlations of the Long Count with the Gregorian calendar have been suggested. J. Eric S. Thompson's correlation is accepted by a majority of specialists. According to it, the Long Count inscriptions cover the period from about 300 A.D. to 900 A.D. The dates given in this article, when referring to this period, are based on that correlation. Evidence from trade relations and stylistic evidence permit the transfer of dates from the Maya area to central Mexico, where no such chronological framework exists.

The method of dating through the radioactivity of organic remains by carbon isotope 14 has been applied to Meso-American materials, but since this method is in the experimental stage, the dates produced cannot be considered as absolutely reliable. Certainly, some of the dates for central Mexico conflict with other sources of evidence.

Ancient Hunters and Plant Gatherers.—The oldest evidences of human occupation in Mexico have been found in the upper layers of a geological formation named Becerra, dating from the very end of Pleistocene times. Mammoths, American horses, and other extinct animals constituted the Becerra fauna.

In the second half of the 19th century, the French Commission Scientifique du Mexique discovered stone implements in geological formations bearing remains of fossil elephants and bisons in the region of Juchipila, Jalisco; in the State of Guanajuato; and near Tacubaya, in the Federal District. In 1946, a small waste flake of obsidian, showing apparent use by man, was found lying below the head of an imperial mammoth (*Archidiskodon imperator*) in a Becerra bed, near Tepexpan, State of Mexico. In 1947, at the same locality and in the same geological layer, was found the skeleton of a man 55 to 65 years old, but there is some controversy about the possibility of this skeleton of so-called Tepexpan man —who would have lived some 10,000 years ago— being an intrusive burial of later date. Finally, in March 1952 another *Archidiskodon* skeleton, also lying in a Becerra stratum, was excavated at Santa Isabel Ixtapan, near Tepexpan. A flint projectile point was found amid the ribs and five other flint and obsidian tools around the skeleton. The projectile point belongs to the type named Scottsbluff, also found associated with the remains of extinct fauna in the high plains region of the United States. Other cultural remains dated at Becerra times are: a fossil llama bone carved in the form of an animal head, found in 1870 near Tequixquiac, and several obsidian, chalcedony, and bone artifacts found by Helmut de Terra after 1946 at Tequixquiac, El Risco, and San Francisco Mazapan. All these localities are in the Valley of Mexico, not far from Tepexpan.

Geologists date the end of the Becerra epoch at about 10,000 years ago. The radiocarbon method yielded dates ranging from earlier than 16,000 to about 4,000 years ago for materials (wood, peat, stems, and roots of aquatic plants) found in the upper Becerra formation. The last date is much later than expected and too recent to be accepted without question. However, the dating of Scottsbluff points in the high plains in the postglacial period from 8,000 to 4,000 years ago may support a date later than 10,000 years ago for the findings at Santa Isabel Ixtapan. Other findings of human skeletal remains or stone artifacts, supposedly very ancient, have been made at different times and in different regions, but for one reason or another full evidence is lacking concerning the antiquity claimed.

For central Mexico, at present, there is a gap in our knowledge of several thousand years between the age of the hunters of mammoths and the earliest known cultures of sedentary farmers from which a continuous sequence of cultural development can be traced up to the time of the Spanish conquest. This gap may be filled by the culture represented by a great number of artifacts, predominantly made of basalt, including grinding stones, found at several places and grouped under the term "Chalco industry." It has been claimed that they represent a culture based on the gathering of wild plants rather than on hunting. Helmut de Terra, the discoverer, dated them from 10,000 to 4,000 years ago, but most of these artifacts were found on the surface, giving no basis for safe geological dating. Furthermore, the association of all these artifacts in a simple tradition of stoneworking is highly questionable. However, the surveys made in northwestern Mexico show that there was a southern extension (in Sonora and perhaps also in Chihuahua) of the prehistoric plant-gathering Cochise culture of the southwestern United States.

Archaic Farmers.—Remains representing the beginnings of agriculture and sedentary life have not yet been found in Mexico. The oldest known cultures of sedentary farmers—called by archaeologists "Archaic," "Formative," or "Middle" cultures—were already very complex. Undoubtedly they were the products of a long tradition of sedentary life and the development of crafts whose antecedents are still to be found.

Not a single complete excavation of an Archaic site has been made; however, the findings made in testing trenches and pits permit one to draw a sketchy picture of life in those times. In what follows, the Archaic cultures in the Valley of Mexico, which are the best known, will mainly be referred to.

Thick fertile alluvial soils, a temperate climate, fish in the lakes and wild fowl living along their marshy shores, and game on the wooded slopes of the surrounding mountains, made the valley very favorable to settlement. Subsistence was based upon cultivation of corn (maize). Beans and squash were probably cultivated, and the products of the agave and prickly pear were probably used. Hunting and fishing were secondary economic activities. The importance of hunting for the first part of this period is attested by the abundance of deer bones found in the middens; later, game became scarcer. Remains of cotton textiles have also been found. The Valley of Mexico is too high for the cultivation of cotton and thus its use surely indicates commercial relations with the neighboring semitropical regions of Morelos, Guerrero, or the southern part of Puebla. These relations are also proved by the distribution of pottery types and terra-cotta figurines. Also, shells from both coasts (from the Pacific in the early period, from the Gulf of Mexico later) which were used for ornaments, and jade and other fine stones from outside the valley reveal extended commercial relations. Tools were made of stone and bone. The basic technological patterns already well established in the Archaic period lasted—with few additions or modifications—until the introduction of European

techniques. Forms, techniques, and motifs of decoration in Archaic pottery are quite elaborate.

Permanent settlements inhabited over long periods of time are indicated by thick deposits of refuse. Little evidence of house types has been found; however, it seems that the walls were of wattle, daubed with mud, a type of wall still in general use in rural Mexico. It is assumed that they were covered by thatched roofs. Only for the last part of the Archaic period do we have evidence of stone building.

Nothing is known about political organization and very little about social structure. Some social differentiation can be inferred from the evidence supplied by burials. Such differentiation does not, however, seem to have attained the complexity of clear-cut class distinctions. The religious ideas of these Archaic farmers manifest themselves characteristically in a fertility cult. This seems indicated by abundant finds of female figurines of baked clay. Such a cult in all probability furnished the basis for the worship of the mother of the gods, the earth goddess, so important in late pre-Hispanic times. Two-headed figurines and above all bipartite masks—expressive of the concepts of life and death—seem to contain the germ of an idea most important in later times, the principle of duality. Conspicuously lacking are formalized representations of gods and symbols associated with a priestly cult, which achieved great development later, in the period of the Classic civilizations.

Radiocarbon dates for charcoal found in early Archaic middens would place the beginnings of this period not later than 1500 B.C. These fall several centuries earlier than the dates accepted by archaeologists before 1950. If we accept the radiocarbon dates, we are faced with a period of about 1,000 years without significant cultural development and with only very minor changes in pottery styles, evidencing a remarkably conservative culture. While this is possible, other considerations lead one to ask for further confirmation of these dates, before accepting them as definitive.

During the last few centuries before the Christian era the homogeneous peasant communities of earlier times were giving rise to more differentiated societies in most of Meso-America. Everywhere in central and southern Mexico, as well as in the highlands and on the Pacific coast of Guatemala, some villages were growing into towns at this time. In the Valley of Mexico, Tlatilco, an extensive site northwest of Mexico City, may well represent an example of this transition. Adequate information on the excavations of this site have not yet been published. Nevertheless, a careful analysis of the evidence found in its great cemetery, excavated in the 1940's, throws light on the changes in social structure corresponding to the development from the homogeneous village culture to the more differentiated and sophisticated town culture. Even before 500 B.C. (according to radiocarbon dating) some towns had enough economic power and control of human resources to build groups of large artificial mounds for religious purposes. Thus, at Cuicuilco, near Tlalpan in the south of the valley, several truncated conical platforms—the largest measuring 390 feet in diameter at the base and 75 feet in height—were raised as bases for altars. This largest mound has a solid mud nucleus and a stone-faced exterior. A large pyramidal mound at Yaxuná, in Yucatán, also belongs to this stage. Other significant new features appearing at this time are calendar and hieroglyphic writing, the earliest examples of which are found in the carved stones with calendric inscriptions uncovered under buildings of later age in the ruins of Monte Albán, near Oaxaca.

Classic Civilizations.—What archaeologists call "Classic" in Meso-America is the period from about the time of Christ, or shortly afterward, to about 900 A.D., when brilliant civilizations flourished and fell. These civilizations had no metal tools, or, for that matter, metallurgy of any kind. Only from about 750 A.D. were some metal ornaments of a gold-copper alloy traded into southern Meso-America (Honduras, El Salvador, and Guatemala) from Panama or Costa Rica.

Systems of overland transportation were poorly developed. Meso-America lacked large animals which might have been domesticated for use as pack animals, such as the Peruvian llama, or for pulling and riding. The wheel was known, but used only for toys. The prevalence of mountainous terrain may then, as now, have inhibited its use in transportation. Goods were transported overland by human carriers. The rivers of Meso-America do not constitute good waterways. Only the lake areas of the Valley of Mexico and of Michoacán (as well as Lake Atitlán in Guatemala) offered facilities for inland water transportation by canoes. This fact accounts for the importance of these areas in pre-Hispanic history. It would seem that maritime transportation along the coast was important only around the Peninsula of Yucatán. However, the productivity of agriculture was developed to the point of being able to support a dense population, part of which was concentrated around large religious centers or in true urban communities. Surplus produce allowed these communities to divert tremendous amounts of energy to the glory of the gods, to the service of their earthly representatives, and to honor the dead.

In central Mexico, the largest city that flourished during this period was Teotihuacán, whose ruins are now about 25 miles northeast of Mexico City. About 300 A.D., the urbanized area of this site covered more than 500 acres; by 700 A.D. it had expanded to cover more than 1,750 acres. We do not know how far the suburbs extended. The nucleus of the city is made up of large temples, of which the most dominant is the great pyramid (the so-called Pyramid of the Sun) which stands 64.46 meters (about 212 feet) high. The temple with the largest ground plan is the square enclosure dedicated to Quetzalcoatl, the Feathered Serpent (a symbol of the water gods), which measures 440 yards on each side. Inside this enclosure there is a pyramid which served as the base for the temple proper, a great ceremonial plaza, and the living quarters of the priests. The great Avenue of the Dead, which forms the axis of the city, and the streets were paved with mortar; there was a complete system of underground drainage. In the residential sections, buildings were densely clustered. The large number of rooms found in the relatively few houses that have been excavated, and their decoration, which often included elaborate murals, indicate that these were the dwellings of an upper class. A cluster of more than 200 rooms and courts, grouped in units of different sizes, excavated in 1935 by Sigvald Linné on the eastern periphery of the site, suggests private houses, possibly for a middle class

of merchants. We have no information about the dwellings of the lower class.

Monte Albán, located on top of a hill, was the metropolis of the central valleys of Oaxaca. Many temples and a great number of well-built tombs, built under the floors of dwellings, have been discovered there. Cobá, in Quintana Roo, was the center of a system of causeways radiating to outlying sites. The longest causeway extends 62 miles west, to Yaxuná. Other important centers of this period were El Tajín, in the coastal plain of northern Veracruz, and Palenque, in Chiapas, one of the westernmost sites of the Maya area. It seems that the flourishing epoch of the Olmec culture of southern Veracruz and western Tabasco should be placed in this period.

The monumental architecture of the Classic period implies a well-organized control of the labor force. Hieroglyphic writing, developments in mathematics such as the use of zero and the positional concept in the writing of numbers, astronomy, and the calendar, mark the achievements of intellectual culture.

Trade was very extensive. It is attested mainly for manufactured luxury items. We also have evidence for trade of either prime materials, such as obsidian, fine-quality flint, or other stones used in the production of tools, or of the finished tools themselves. A fine type of pottery, probably produced in southern Puebla, was traded as far as Teotihuacán in the Valley of Mexico, to Colima in the west, and to Copán in Honduras. Food must have been an important trade item, considering the great urban population, which could not have been self-sufficient. The supporting area of the largest centers, such as Teotihuacán and Monte Albán, must have been very large.

The importance of temples and the development of religious art (see the section *Pre-Hispanic Art*) seems to indicate that religion was the main integrating force of society. The main deities were the water gods, the gods of vegetation and corn, the god of fire, and in the southern regions (Oaxaca and the Maya area) a bat god. Noteworthy by its absence is the cult of the gods of war.

Most of the settlements are located in open ground, with obvious disregard for defense, and lacking—so far as is known—any artificial protective works. The ruins of Monte Albán are an exception to this, in that they are located on top of an easily defensible hill rising 1,300 feet above the surrounding valley. Nevertheless, the excavations have failed to produce any indication whatever that the site was selected with defensive purposes in mind or that it was at any time used as a fortress.

Transition Period.—This location of the sites and absence of defensive works and the absence of representations of warriors in art at the peak of the Classic period seem to indicate that external relations were predominantly pacific. Later, warfare acquired greater importance. Warriors and battle scenes became prominent in art. According to present evidence the earliest examples of such representations occur in the Usumacinta River drainage (western Maya area) and are dated about 630 A.D. Central Mexican tradition tells us of the conquest of Cholollan (modern Cholula, near Puebla)—formerly a center of the Teotihuacán culture—by the Olmec-Xicalanca people, about the end of the 8th century. Approximately at the same time, Teotihuacán was violently destroyed and never rebuilt. Monte Albán was abandoned, its buildings fell into ruin, and the site was subsequently used only as a burial ground. Farther south, one after another the Mayan centers of civilization in the previous centuries were also deserted. The causes of this general crisis are not yet known, but the consequences were unquestionably a change from societies patterned on a seemingly theocratic basis to more secular-militaristic ones. The settlement pattern changed accordingly. After the 9th or 10th centuries many cities and towns established in open country were protected by stone walls, or by palisades and moats. In addition, many settlements with large, permanent populations were located on hilltops and were, in most cases, solidly fortified as well.

It seems that the ruins of Xochicalco, in Morelos, correspond to the epoch of transition between this period and the following one, or about the 9th to 10th centuries. The site is composed of three parts: the acropolis, on a steep hill, a ceremonial and residential section—seemingly for the upper class—surrounded by ramparts and moats; the citadel on top of a neighboring, higher hill; and a suburban area on flat ground, protected by these hills and by deep ravines.

Toltec Period (c.900 A.D.–c.1200 A.D.)—About the beginning of the 10th century a conqueror called Ce Tecpatl Mixcoatl entered the Valley of Mexico. He was the chief of a barbarian people arriving from the northwest (possibly from Zacatecas, Jalisco, or the Lerma River basin). Mixcoatl established his capital at Culhuacán in the Valley of Mexico, and extended his conquests in the south to the neighboring Valley of Morelos and northern Guerrero. Soon, these invaders absorbed the civilization of central Mexico. Such a process of acculturation was repeated later, after the fall of Tollan, by the Aztecs and other Chichimec groups. Mixcoatl's son, Ce Acatl Topiltzin, is the most important figure in Toltec history. He was the founder of Tollan (now Tula, Hidalgo), where he established the capital of his empire. The name Toltec is derived from the name of this city. Internal disturbances put an end to the rule of Ce Acatl and he was forced into exile. A new dynasty began at Tollan, with Matlacxochitl as the first king. Famine, epidemics, and war mark the history of this period, until Tollan was destroyed and Huemac, its last king, was killed or hanged himself in a cave on the Hill of Chapultepec. A dispersion of the Toltec lords took place. They took refuge in their possessions to the south and the southeast. At that time the Chichimecs took over most of the former Toltec territories in central Mexico; however, Toltec tradition was kept alive at Culhuacán. (See also TOLTECS.)

In Yucatán, local tradition records the arrival of foreign invaders toward the end of the 10th century. Their legendary leader was named Kukulcán. This title is the literal translation in Maya of the Nahua word Quetzalcoatl (Feathered Serpent), the title of Ce Acatl Topiltzin. There is no doubt of the connection between these events and the history of Tollan. Excavations at Tula (Tollan) and at Chichén Itzá, in Yucatán, have demonstrated close cultural connections between the two sites. But there are reasons to believe that this leader was not the same Ce Acatl referred to previously. The title Quetzalcoatl or Kukulcán seems to have been applied to different men at different times.

Toltec invaders also reached the highlands of

Guatemala. They conquered the local populations belonging to the highland branch of the Maya and established dynasties which lasted until the Spanish conquest.

It would seem that during the Toltec period the valleys of Puebla and Tlaxcala, and parts of the valleys of Mexico and Morelos, were under the domination of the Olmec-Xicalanca people, mentioned above as conquerors of Cholollan about the end of the 8th century. It is believed that they were people of Chocho-Popoloca and Mixtec origin, related to or identical with the Nonoalca, one of the ethnic components of the Toltecs. In Oaxaca, Mitla, a site famous for the beautiful stone relief mosaic on the walls of the palaces, flourished during this period, after the decline of Monte Albán.

It was during the Toltec period that metallurgy became widespread in Meso-America. However, metal was used mostly for ornaments. For the epoch prior to 900 A.D., there is at present no evidence of metal in Meso-America besides that brought into the southern areas through trade with Panama, previously mentioned; however, metallurgical techniques could be older than this date in the archaeologically little-known area of western Mexico. In this area, copper (or bronze) metallurgy was well developed in later times, and cast copper bells, apparently from western Mexico, were traded as far north as southern Arizona at about 1000 A.D.

From About 1200 A.D. to the Spanish Conquest.—In central Mexico, a troubled period followed the fall of Tollan. Previous plagues and wars had resulted in serious depopulation, and the outcome of political disintegration created a chaotic situation. At that time, different peoples —collectively designated by the Indian historical sources as Chichimecs—invaded the Valley of Mexico and the neighboring regions. Among them were the Aztecs. The term "Chichimec" requires clarification. It was used to designate peoples of very different cultural types and ethnic origins, including: (1) the northern food-gathering nomads; (2) farming peoples from the north, culturally simpler than the civilized peoples of central and southern Mexico; and (3) the descendants of civilized colonists established in the northwest in former times, returning to central Mexico after the fall of Tollan. Indian history emphasizes the importance of the role played by peoples of the first type during the period of the invasions, and by their descendants in the history of the following centuries. Some modern scholars overstress this point, and the author believes that critical analysis of the historical sources will prove that most of the invaders, and certainly those who were to provide the politically dominant element of later centuries, belonged to the second and third types. As a result of the movement of peoples, northern territories previously occupied by sedentary farmers were abandoned to nomadic food gatherers. The frontier of civilization thus receded somewhat in the direction of the south.

The 13th century is an obscure period during which the newcomers established new dynasties in the Valley of Mexico and conquered the dominions of the Olmec-Xicalanca people and their allies in the southern part of the valley and in Morelos, Puebla, and Tlaxcala. Cholollan (Cholula) fell to the Chichimecs about 1292 (the traditional date, 1168, has been corrected by more recent studies in pre-Hispanic chronology), and the Olmec-Xicalanca were expelled toward the northeast and southeast.

City-States in the Valley of Mexico.—Out of this confusion emerged, at the end of the 13th century and the beginning of the 14th, several city-states in mutual competition for hegemony. There was an Otomí kingdom, with its capital at Xaltocan in the north of the Valley of Mexico, whose territories extended beyond, as far north as Oxitipan on the border of the Huastec region —the Huastecs (or Huaxtecs) being an isolated Maya tribe living in northern Veracruz. It lasted until 1395, when the Tepanecs conquered Xaltocan.

The other major powers in the valley were, at first, Culhuacán—where the last vestige of Toltec tradition and legitimacy was kept alive—and a new Chichimec kingdom, founded by the invaders, whose capital was originally established at Tenayocan (in the Valley of Mexico northwest of Mexico City) and was later moved to Tetzcoco (or Texcoco). Culhuacán was decisively defeated in 1347, and an 80-year period of Tepanec supremacy followed, with Azcapotzalco as the capital and Coatlichan, Amaquemecan (now Amecameca), Huexotzinco (now Huejotzingo), and Cuauhnahuac (now Cuernavaca) as allies; Tetzcoco being relegated to a subordinated position. The Tepanecs had arrived in the Valley of Mexico from the neighboring Valley of Toluca. Ethnically they belonged to the group Otomí-Matlatzinca-Mazahua. The core of their dominions was the regions in the northwestern section of the Valley of Mexico and north and west of it, occupied by the Otomí and related peoples. At its peak, just before its fall, the Tepanec Empire expanded to the east and south, incorporating—through conquests and political alliances—territories occupied by Nahua peoples, and covered over 15,000 square miles of central Mexico—from Itzmiquilpan (now Ixmiquilpan) in the north to Tlachco (today's Taxco) and possibly to the Balsas River in the south, and from Tollocan (modern Toluca) and Ixtlahuacan in the west to Tollantzinco (modern Tulancingo, in Hidalgo) and Huexotzinco in the east. Besides the intensively cultivated and densely populated Valley of Mexico and other plateau territories, the Tepanecs thus dominated the semitropical lands of Morelos and northern Guerrero, which supplied the plateau with cotton, not cultivated in higher altitudes, native paper, jade, copper, and feathers.

To curb the danger of rebellion of the vassal lords, Tezozomoc, only king of Azcapotzalco during the period of Tepanec supremacy, imposed several of his sons as kings of different vassal city-states, murdering the kings of local dynasties when necessary. However, at Tezozomoc's death (1427), a rebellion broke out under the leadership of Itzcoatl, king of Tenochtitlan (see AZTECS) and Nezahualcoyotl, legitimate heir to the kingdom of Tetzcoco. This rebellion had the characteristics of a civil war in that public opinion within each city-state was divided. Bitter internal fighting and political murders were the result. The success of the rebellion was favored by dynastic troubles, because Tezozomoc's son and successor, Maxtla, not being the first born, was not the legitimate heir and was considered a usurper. The rebellion had the help of the Tlaxcalans who, as eastern neighbors of the Tepanec Empire, were probably fearful of its expansion. The war began with the storming of Azcapotzalco (1428) and ended in 1431 when the rebels took Coyoacán, Maxtla's own fief, and lib-

BOUNDARIES
Empire of Azcapotzalco, c. 1425.
Aztec Empire, 1519.
The Isthmus of Tehuantepec and part of Chiapas, conquered by the Aztecs but not incorporated in the empire. There were Aztec garrisons, but no tribute to the empire.
Tarascan Kingdom, 1519.
Tarascan conquests in the 1460's, subsequently lost.
Northern boundary of the sedentary peoples, 1519. Nomadic food gatherers to the north, sedentary farmers south and west of the line.
Modern political frontiers.
Outline of Central Plateau.

erated Tetzcoco. As a result of the war, and to fill the political vacuum left by the destruction of the Tepanec Empire, a triple alliance was established, including the two victorious powers (Tenochtitlan and Tetzcoco) and Tlacopan, as a minor member representing the vanquished. Despite frictions between the three confederate powers this confederacy proved successful in maintaining the political stability of the valley until the coming of the Spaniards, and in uniting forces for external conquests.

Between 1431 and 1440, Nezahualcoyotl extended the power of Tetzcoco toward the northeast, to Tziuhcoac on the border of the Huastec area.

Aztec Expansion.—Itzcoatl, for his part, extended the conquests of the Aztecs toward the south, through Morelos and northern Guerrero to the Balsas River. From the rule of Montezuma I (Moteczuma Ilhuicamina; r. 1440–1468) on, the Aztecs of Tenochtitlan gained hegemony over the confederacy and subordinated the foreign policy of their allies to their own ends. Montezuma I extended his conquests up to the Gulf coast in central Veracruz. Axayacatl (r. 1469–1481) completed the encirclement of Tlaxcala and conquered the Matlatzinca territories of the Valley of Toluca in the 1470's, though he failed in his effort to invade Michoacán. Ahuitzotl (r. 1486–1502) was a great conqueror. He conquered a part of the Huastec area to the northeast. To the south, he reached the coast of Guerrero and established bases in Oaxaca which facilitated the conquests of his successor. He crossed the Isthmus of Tehuantepec, conquered the Soconusco (the Chiapas coast) and established garrisons in the Chiapas highlands up the modern Guatemalan border. Montezuma II (Moteczuma Xocoyotzin; r. 1502–1520) overcame the Mixtecs and Zapotecs of Oaxaca, with the exception of the powerful Mixtec lordship of Tututepec on the Pacific coast, which maintained its independence until the coming of the Spaniards.

Thus in less than nine decades the Aztecs and their allies built an empire which comprised about 75,000 square miles and between 5 and 6 million people. These conquests did not aim at the acquisition of land for colonization, but rather to incorporate the political and military resources of the conquered peoples into the empire, to open trade routes, to dominate markets, and to obtain tribute. The tribute books of the empire give us information about its extent, the organization of its provinces, and the heavy tribute which they had to pay. Two copies of these tribute books have been preserved. One, the *Matrícula de Tributos* in the Museo Nacional de México, was probably painted for Hernán Cortés; the other, *Codex Mendoza* in the Bodleian Library, Oxford, was painted for the first Spanish viceroy, Antonio de Mendoza.

Due to environmental and cultural factors, the Aztecs did not attempt to expand northward into Chichimec territory. Geographical conditions discouraged colonization, and it was impossible to extract tribute from the nomad hunters. Their conquests to the east and to the south were made in territory occupied by civilized groups, politically fragmented into rather small principalities. Whenever they encountered other centralized states, they met with failure.

Tlaxcalans.—For the reason just mentioned, the Tlaxcalans (or Tlaxcaltecs) to the east of the Valley of Mexico, with about 200,000 people occupying a territory of about 1,600 square miles, were successful in rebuffing the Aztec attacks. This was true in spite of the fact that over a period of about 60 years, until 1519, the Tlaxcalans were completely surrounded by provinces of the Aztec Empire, and thus subjected to a severe economic blockade and constant military pressure. Systems of fortification encircled the territory of Tlaxcala on both sides of the frontier.

Tarascans.—To the west, after the conquest of the Valley of Toluca by the Aztec king Axayacatl in the 1470's, the only enemy left was the Tarascan kingdom of Michoacán. Axayacatl's attempt to invade Tarascan territory met with a crushing defeat at Taximaroa (now Ciudad Hidalgo, Michoacán). From then on, the two states were involved in constant warfare, and systems of forts and garrisons were maintained along the disputed frontier.

At the time of the Spanish conquest, the Tarascan kingdom comprised about 25,000 square miles and a population estimated at 1,000,000. The core of the kingdom was the region of Lake Pátzcuaro and the sierra to the west of the lake. The Tarascans showed strong social and political cohesion and the same expansionist tendencies as the Aztecs, although they were less urbanized than the inhabitants of the Valley of Mexico. The integration of the Tarascan state began about 1370, under the rule of Tariacuri, who conquered northwestern Michoacán and adjacent Jalisco, as well as the middle Balsas River basin to the south. When he died the kingdom divided into three parts. Pátzcuaro, Tzintzuntzan, and Coyuca (now Coyuca de Catalán, Guerrero) were the capitals of these splinter states. King Tzitzic Pandacuare reunited the three principalities, extended his conquests toward the southwest, and reached the Pacific coast in the 1460's. He was responsible for the defeat of Axayacatl's attempted invasion at Taximaroa. Subsequently, the Tarascans lost their dominions on the Pacific coast, but proved successful against the Aztecs. In the early 1500's they threw back another attempted invasion at Indaparapeo, and exerted aggressive pressure on the southern part of the Tarascan-Aztec frontier. On the northern frontier, Tarascan activities remained limited to forays against the Chichimecs in El Bajío (chiefly the modern states of Guanajuato and Querétaro) in order to protect their border, without attempting a permanent conquest of the region.

For the history of the Maya see the separate article MAYA.

25. SPANISH CONQUEST AND COLONY. The Spanish conquest of Mexico at first represented a cultural clash but eventually there developed an amalgamation of cultures. On the one hand was the Spanish culture, with a strong medieval tinge; on the other, the Indian, in central Mexico dominated and made homogeneous by the Aztecs. The conquerors had varied backgrounds, but most of those coming to the new world were

concerned with the dual purpose of propagating the Catholic faith and of raising themselves in the social scale. They were men of strong ambition.

The conquest started from Cuba. In 1517 the expedition of Francisco Hernández (or Fernández) de Córdoba reached Yucatán, where it was defeated in the bay called Mala Pelea (literally, bad fight), and explored the coast of Campeche. In 1518 a second expedition, under Juan de Grijalva, left Cuba and explored the coast as far north as San Juan de Ulúa, off the modern city of Veracruz.

The results obtained encouraged other adventurers who, headed by Hernán Cortés (1485–1547), took part in another expedition ordered by the Cuban governor, Diego Velázquez. Although chosen by the governor, Cortés had to balk several attempts by the former to replace him, and on Feb. 18, 1519, set sail without authorization. The stages of the voyage were: Cozumel Island, off Yucatán; the Grijalva River, Tabasco; the Isla de Sacrificios and San Juan de Ulúa; and a final landing near the site of modern Veracruz.

The Aztec emperor, Montezuma II (more correctly Moctezuma), frightened by omens and the legend of Quetzalcoatl, which prophesied a return of that god from the east, did everything short of violence to prevent Cortés from advancing inland. Cortés, however, noting the dissensions and fears within the country, proceeded to convert his expedition into an occupation.

The municipality of Veracruz was founded April 27, and communications with Velázquez were broken off. Cortés then arranged to have the municipal authorities of the new town select him captain general, and a ship was sent to Spain to secure the royal ratification. The other ships were burned and, on August 14, Cortés led his expedition inland toward the Aztec capital of Tenochtitlan, on an island in Lake Texcoco on the site of modern Mexico City, leaving a small garrison at Veracruz. During the advance, an alliance was made with the Tlaxcalans, perennial enemies of the Aztecs, who after testing the power of the Spaniards in two battles became their allies and gave a fundamental assistance to the conquest.

In October, Cortés reached Cholula, where, confronted with attempted treachery, he and his men killed many hundreds of the inhabitants. Montezuma's hopes of stopping the expedition were frustrated and he succumbed to fatalistic despair. The Spaniards reached Tenochtitlan on Nov. 8, 1519. Hoping through the emperor to control his subjects, Cortés seized Montezuma soon after, but it was clear that the Aztecs would not long submit.

When the city's population was at its most antagonistic to the Spaniards, Pánfilo de Narváez, sent by Governor Velázquez, arrived in Mexico to arrest Cortés. Leaving Pedro de Alvarado (1495?–1541) in command of Tenochtitlan, Cortés returned with a small force to Cempoala, where he surprised and captured Narváez and enlisted his men in his own force. In Tenochtitlan, meanwhile, in the mistaken belief that a gathering of Aztecs for a religious ceremonial was a prelude to an attack on the Spaniards, Alvarado had massacred a large number of Indians. Cortés returned to find the Spaniards besieged. Montezuma tried to pacify his people but was stoned and killed.

On the night of June 30–July 1, 1520, the Spaniards and Tlaxcalans, carrying away much of its wealth, fought their way out of the city over the causeways which connected it to Tlacopan on the mainland, with the loss of many men. Those taken prisoner were sacrificed. Cortés wept over his losses on what is remembered as *la noche triste* (the dismal night), and the Spaniards retreated to Tlaxcala.

Montezuma's brother, Cuitlahuac, defender of Tenochtitlan, became emperor. He renewed his alliances with the Indian lords, but the populace was weakened by epidemics, in one of which Cuitlahuac died. He was succeeded by the last of the emperors, Cuauhtemoc.

Cortés made several expeditions to prepare the taking of Tenochtitlan; the first from Segura de la Frontera (now Tepeaca, Puebla), the second from Texcoco, the last from south of Tenochtitlan. Having done this preparatory work, the next year, with forces enlarged by groups recently arrived from Cuba, he again attacked the Aztec capital. The siege began on May 26, 1521, lasting until August 13, and destroying the city. Cuauhtemoc was captured, and later taken as a hostage by Cortés on his expedition to Honduras in the course of which he was executed (1525).

Once Tenochtitlan had been taken, Spanish expansion spread in several directions—to the north with the expedition (1522) of Cortés to the Pánuco River; to the west with the expedition (1522–1524) of Cristóbal de Olid into Colima and Jalisco; and to the northwest with the expedition (1535) of Cortés to Lower California. The areas of modern Guatemala and El Salvador 1526. Olid led an expedition into Honduras (1524), where he came in conflict with Spaniards advancing from the south. Having overcome these, he renounced his allegiance to Cortés, but was defeated by Francisco de las Casas and killed. Cortés himself then undertook an arduous expedition to Honduras, 1524–1526. Numerous expewere conquered by Pedro de Alvarado in 1524–ditions were made against the Maya in Yucatán, but they were not conquered until the campaigns of Francisco de Montejo the Younger in 1540–1546.

COLONY

The conquest did not end with the epic period; part of the Central Plateau and the northern part of the country remained to be settled. The dynamics of the movements which occupied these regions grew out of the characteristics of the colonizing groups. Because the traditions of inheritance within the Spanish family, based on primogeniture as well as custom, offered little hope for the younger sons, these tended to become adventurers. Land grants given by the crown covered a vast territory, sparsely populated. Those unable to obtain grants moved on still farther to unclaimed land.

Social and Economic Organization.—The Spanish colonizer tended to superimpose, both physically and socially, his community on the native ones. He subordinated the Indian population to his own juridical and economic institutions, placing it at the bottom of the seigniorial organization, topped by himself. Since the colonizer had come to America in search of social betterment, which in 15th and 16th century Europe was based on the seigniorial system, labor was performed by the lower strata, with the upper classes supervising or performing military duties.

These upper classes also included the missionaries and governmental officers, generally from Spain.

When the territory had been conquered, it was organized in conformity with contracts made between the king and the conquerors. Booty obtained directly from war, such as Indian slaves, pearls, gold, and feathers, must be differentiated from the lasting privileges, such as the marquisates, *encomiendas,* and *repartimientos* granted by the king. Holders of such privileges had the double duty of exploiting the Indians and of giving them a tie with the colony. They were charged with assimilating the Indians into the new social and economic order, besides converting them to the faith.

Indian Labor and the Problem of Conscience.—Labor for agriculture, mining, industry, and construction in the colony was always supplied principally by the Indians, although Negro slaves and mestizos (persons of mixed Spanish and Indian blood) were also used. Much of the profuse labor legislation was designed to protect these laborers against abuse.

Indian enslavement was one of the important results of the conquest, and was considered its logical consequence; but while the Spaniards applied the Roman concept, under which a slave was equivalent to a "thing," slavery among the Indians consisted of various grades of liberty, only seldom (in the case of slaves sold in the markets) descending to the Roman concept. The abuses of the conquerors and these differences in concepts of slavery led to protests being sent to the king by ecclesiastical groups, government officials, and soldiers. The missionary and historian Fray Bartolomé de las Casas (1474–1566) should be remembered among the distinguished leaders in this struggle for Indian freedom.

The Spanish crown was exposed to pressures from conflicting sides. On the one hand it was sympathetic to the spiritual and religious viewpoint; on the other, it saw the material value of slavery as an economic factor. The crown hesitated until Nov. 20, 1542, when the Leyes Nuevas (New Laws) established freedom as a principle and forbade the acceptance of slaves sold by Indians. Even "just" wars were no longer to be considered legal sources of slaves and the slavery of women and children was forbidden. The institution endured as a punishment for those who resisted the colonial system. The Indian remained as a serf, tied by the obligations of paying tribute and providing personal service. The comparative liberty of the Indian, however, furthered the slavery of the Negroes, who were brought to New Spain by foreign traders to supply the need for labor.

Up to 1549, the principal device for utilizing Indian labor was the *encomienda.* This was a royal concession granting a Spaniard (usually one of the conquerors) part of the tribute in goods and labor that was due the king from a particular group of Indians, in return for which the *encomendero* was obligated to protect his Indians, supervise their education and religious indoctrination, and provide vocational training. Indians rendered personal services to the *encomendero* for no more than 20 days consecutively, with a month elapsing between each period of service. All women, and children under 12, were exempt from personal service.

First introduced into the Antilles, with disastrous consequences to the Indian population, the *encomienda* as organized by Cortés in New Spain was designed to avoid the worst abuses of the Antilles. In any case, some means of utilizing Indian labor was necessary if the colony were to be maintained, and for their part, the conquered Indians needed protectors who had a personal interest in their welfare.

Nevertheless, the extension of the *encomienda* system in New Spain was opposed by the crown both in the name of humanity and because, with its feudal implications, it challenged the growing concept of centralized absolute power. On June 20, 1523, Charles V issued the Cédula de Valladolid, designed to bring the *encomiendas* to an abrupt end, but enforcement was impossible in the face of furious colonial opposition and the order was nullified.

A similar attempt was made in the Leyes Nuevas of Nov. 20, 1542, which forbade the granting of new *encomiendas,* canceled those that were held without legal title and those held by viceroys, governors, royal officials, prelates, monasteries, and hospitals. *Encomiendas* were no longer to be passed on by inheritance; on the death of the *encomendero,* his *encomienda* was to revert to the crown. The intent was the complete abolition of the system in a generation, but again the royal commands were not enforced. With the *Cédulas de Malinas* of Oct. 20, 1545, Charles retreated from his position, but did insist on abolishing personal services to the *encomendero.*

After 1573, the privileges of an *encomendero* were reduced to the right to collect a tribute from his Indians. He was still obligated to protect and instruct them, but no longer had seigniorial power over them. The *encomiendas* that remained were extinguished during the 18th century.

As the *encomienda* system was whittled away, it was replaced by a forced *repartimiento.* Under this ancient Spanish method of recruiting labor, the Indians were forced to work at agriculture, mining, and construction, but their services were on a temporary basis, under contract, and the employer to whom they were consigned had to pay wages.

Government.—At first, the government was subordinate to the Audiencia of Santo Domingo. But this changed when Spanish dominion extended throughout the continent and the home government began to centralize. Cortés organized the colony on Oct. 30, 1520, naming it Nueva España (New Spain), and in 1522 was named governor and captain general. Its center was erected on the site of modern Mexico City and it included all of modern Mexico, somewhat later the captaincy general of Guatemala, and after the discovery of the western shores of the modern United States it extended northward as far as Alaska.

Royal treasury officials took over the government during Cortés' expedition to Hibueras (Honduras), which began on Oct. 12, 1524. During his absence a conflict broke out between his followers and more newly arrived officials. This subsided upon his return in 1526, but late in the next year he returned to Spain to defend himself before the king.

The first *audiencia,* a supreme court with executive functions, was sent from Spain and assumed the conduct of public affairs from December 1528 to the end of 1530, a period noted in the history of Mexico for its destructiveness. These first *oidores* (members of the *audiencia*) were its president, Beltrán Nuño de Guzmán, and Alonso Parada, Francisco Maldonado, Juan

Ortíz de Matienzo, and Diego Delgadillo. Parada and Maldonado died shortly after reaching Mexico. Guzmán, Matienzo, and Delgadillo remained, and made themselves wealthy by despoiling Cortés, his captains, and his soldiers, and by exploiting the Indians without restraint. They appropriated 100,000 Indians in *encomienda* and levied such heavy tributes on them that, besides storing up great wealth for themselves, the exploiters had enough grain and clothing left over to sell to the public.

Cortés returned to New Spain in 1530, no longer as governor, but only captain general and marquis of the Valley of Oaxaca, and the next year saw the arrival of the second *audiencia* to replace the first. More carefully selected than their predecessors, its *oidores* were Sebastián Ramírez de Fuenleal, bishop of Santo Domingo, Juan Salmerón, Francisco Ceynos, the celebrated Vasco de Quiroga, and Alonso Maldonado. All worked in cooperation with the first bishop of Mexico, Juan de Zumárraga (1468–1548), who had opposed the excesses of the first *audiencia*. Aside from their regular duties, they conducted trials of *residencia* to hear charges against the first *audiencia*, and took a census of Cortés' approximately 23,000 vassals, as well as making a general inquiry into the complicated activities of the conqueror of Mexico. The *oidores* were in the position of defenders of the crown's interests against the ambitions of Cortés, but on the whole they performed this duty without resorting to the violence that had marked the actions of their predecessors. In 1540, after a long conflict with the first viceroy, Cortés left New Spain, never to return.

Viceroyalty.—The first viceroy of New Spain, Antonio de Mendoza, was appointed in 1529 and held office from November 1535 to October 1550.

Although the viceroys seldom held office for more than six years, the frequent turnover was offset by the strictness of the system, which provided for a trial of *residencia* at the end of each viceroy's term. A new viceroy followed the *relación* (report) of his predecessor and heard the opinion of the *oidores*. He presided over the *audiencia*, and his functions were those of governor, superintendent of the royal treasury, and vice patron of the church.

The *audiencia* was an important juridical institution. Its decisions in relatively important cases were final; in cases of great importance an appeal could be made to the Council of the Indies in Spain. Its president, or all its members, substituted when the viceroy was absent, to maintain the administrative functions.

Lower levels of government were administered by provincial governors, and by *corregidores* and *alcaldes mayores*, officials with similar functions, who represented the royal authority in smaller districts. Special *corregidores* were appointed to govern the Indian towns. In addition there were the autonomous *municipios* (municipalities) governed by their own councils (*ayuntamientos*).

The personalities of the viceroys are important because they were the direct representatives of the king, in whose person was centered all government power, legislative, judicial, and administrative. Since the king was recognized as God's representative, the government's right to rule was considered both natural and divine.

Antonio de Mendoza made an auspicious beginning and set an impressive example for his successors. He worked closely with the second *audiencia*, and on the whole his government was marked by justice and order, establishing an important tradition of orderly administration in New Spain. Mendoza also waged several difficult Indian wars, notably the one called the Mixton War (1541) in Jalisco, and in 1540 sent a futile expedition under Francisco Vázquez Coronado in search of the legendary Seven Cities of Cíbola.

His successor, Luis de Velasco, in office October 1550–July 1564, was outstanding in promoting the spread of Spanish civilization northward, and his protection of Indian rights earned him the title "Father of the Indians."

Another noteworthy viceroy was Fray Payo Enríquez de Rivera, in office 1673–1680. Although his administration was routine and unexciting, it was just and progressive. Significant material gains were made and the viceroy was well loved.

Royal Control.—The viceroy was the king's personal representative in New Spain. Generally, the king governed his colonies through the Council of the Indies (Consejo de Indias), but at times he sent direct royal orders. Organized by Charles V in 1524 to advise him on matters concerning the Indies, the council came to exercise supreme legislative, executive, and judicial power over the colonies until the creation of the Universal Secretariat of the Indies in 1714 reduced it to the functions of a supreme court. While the Spanish Constitution of Cádiz was in force (1812–1814, 1820–1824), the council disappeared, but it was re-established for ten years, 1824 to 1834.

The Casa de Contratación (House of Trade) was another institution fundamental to the administration of the colony. Founded in 1503, little by little it assumed the management of all commerce in the Indies, as well as immigration, exploration, and legal problems involving merchants and shippers. Situated in Seville, the only port in Spain legally authorized to handle shipping to and from the Indies, the Casa had absolute control over all legitimate colonial commerce. The ports of entry in New Spain were Veracruz on the Gulf and Acapulco on the Pacific. The result of this monopoly was harmful to the Spanish Empire, since large-scale smuggling by both Spaniards and foreigners flourished, and a consequent contempt for law and authority was fostered. The Casa de Contratación was transferred to Cádiz in 1717.

The exploration activities of the Casa de Contratación were also of great importance. Its navigation school was directed by Amerigo Vespucci (1451–1512), who was assisted and succeeded by other world-renowned seamen. The merchant tribunals known as *consulados*, which were established in Spanish America and later throughout the world, developed out of the Casa de Contratación.

Mining.—This industry was fundamental to the prosperity of New Spain, as well as old Spain. It was the output of American mines that made Spain the first power of the Western World. All mines and subsoil rights belonged to the crown, but were rented to those who discovered them, the crown obtaining a fifth (the royal *quinto*) of the output. Failure to work the mine was grounds for expropriation.

Mineowners were a favored class, enjoying numerous political and social privileges. All the prime materials for mining were tax-free. Mercury, essential for the extraction of silver by the

patio process, was allotted in proportion to ore production. To expedite their affairs, the mine-owners formed the Cuerpo de la Minería de la Nueva España on May 4, 1774. The organization conducted a court, a bank (Banco de Avío), and in 1792 established a college of mining (Real Seminario de Minería de México) to train technicians. A mining code, the Ordenanzas de Minería, was formulated May 22, 1783, while José de Gálvez was minister of the Indies, under the wise direction of Joaquín Velázquez de León.

Of the 500 mines in New Spain, the richest was La Valenciana in Guanajuato, which at its peak in 1800 produced some 3 million pounds troy of silver. Total production of the mines of New Spain from 1537 to 1821 was 2,151,581,961 pesos, with the peso during that period roughly equivalent to a dollar.

Church.—One of the major objectives of the Spanish crown in undertaking the conquest of the Americas was the conversion of the natives to Catholicism. In addition, the clergy, particularly the great religious orders, was the main source of education in the colonies, both secular and spiritual education being dependent on the development of religious institutions.

In order to coordinate ecclesiastical administration and relations between church and state, problems closely intertwined in colonial development, the Spanish rulers Ferdinand and Isabella obtained the right to control the relations between the papacy and the church in America. This important concession, known as the *patronato real* (royal patronage), was granted by the Vatican in several bulls between 1493 and 1508. Later, sweeping concessions allowed royal intervention in parish policies, church doctrine, administration of the sacrament, choral services in the cathedrals, rules of religious orders, church elections, and in general in all matters except those referring to faith and general discipline. In spite of this unusual distribution of authority, relations between church and state were usually amicable during the colonial period.

The first Catholic diocese was established at Tlaxcala in 1527, upon the arrival of its bishop, Julian Garcés, a Dominican. Subsequently, ten more were established. These dioceses, working through their parishes, which nearly always had a hospital and a school, were centers of education, public welfare, and social life. At the end of the 16th century, there were 474 parishes, and by 1810 there were 1,070.

The main task of the ordinary clergy was the establishment of the regular church in New Spain, while members of the various religious orders busied themselves with the conversion of the Indians. A good many of the methods used by religious missionaries originated in New Spain and were, little by little, adopted by the lay clergy.

Franciscans.—This order was the first to reach New Spain. Three Franciscan friars of Flemish origin arrived at Veracruz on Aug. 13, 1523: Juan de Tecto (Dekkers), Juan de Aora (Van Den Auwera), and the noted educator, Pedro de Gante (that is "of Ghent"). They quickly applied themselves to learning the Indian languages, and another famous group, known as "the Twelve," reached Veracruz on May 13, 1524, entrusted with a mission from Pope Adrian VI. They were Martín de Valencia, their leader; Martín de Jesús (or de la Coruña), who later led the missionaries who with Cortés attempted to colonize Lower California in 1535–1536; Francisco de Soto, Francisco Jiménez, Juan de Ribas, Juan Suárez, Antonio de Ciudad Rodrigo, Toribio de Benavente (known as Motolinia), who was known for his charity and poverty, later a historian and one of the founders of Puebla; García de Cisneros, and Luis de Fuensalida, accompanied by two lay brothers, Andrés de Córdoba and Juan de Palos.

In New Spain the order was organized in five "provinces": Santo Evangelio in the capital (founded 1535), San José of Yucatán (1539), San Pedro y San Pablo of Michoacán (1565), Santiago of Jalisco (1606), and San Francisco of Zacatecas (1606). Until they became provinces, the *custodias* of Yucatán, Michoacán, Jalisco, and Zacatecas were subordinate to the Province of Santo Evangelio. Similarly dependent were the *custodias* of Peru, Nicaragua, Guatemala, and Florida. The Franciscans carried Christianity to almost all of the country and provided missionaries of high qualities. Besides contributing such noted men as Juan de Zumárraga, first bishop of Mexico, and the saintly Marcos Ramírez de Prado, bishop of Michoacán from 1640 to 1666, they wrote many of the basic works on history and the Indian languages.

Dominicans.—The first Dominicans to reach New Spain were twelve that arrived in company with a royal official, Luis Ponce de León, July 2, 1526. Five died the first year, and four returned to Spain. Gradually, they renewed and increased their forces and established four provinces: Santiago of Mexico (1532), San Vicente of Chiapas and Guatemala (1551), San Hipólito of Oaxaca (1595), and the Province of Puebla (1656). In a famous controversy over the nature of the Indians—were they rational human beings with souls to be saved, or a nonhuman species?—the Dominicans were furiously involved under the leadership of Bartolomé de las Casas in defense of Indian rationality. Although it converted Indians on a mass basis, the order later entertained doubts concerning the religious capacity of the Indian population.

Through the University of Mexico and the Inquisition, the Dominicans displayed their characteristic orthodoxy and mastery of doctrine. Prominent leaders of the order were Las Casas, Bishop Garcés, and Antonio Alcalde, who became bishop of Yucatán in 1767, and in 1771 bishop of Guadalajara, where he founded the university and charitable institutions.

Augustinians.—The first Augustinians landed at San Juan de Ulúa on May 22, 1533. Two provinces were established: El Santo Nombre de Jesús of Mexico (1587) and San Nicolás de Tolentino of Michoacán (1602). The special role of the Augustianians was the organization and direction of Indian communities. They did valuable missionary work and were distinguished as teachers in the University of Mexico.

Jesuits.—The Jesuit Province of Mexico was founded by 17 men who reached Mexico on Sept. 28, 1572. The province lasted 195 years, a brief life compared to those of the other orders. The important influence of the Jesuits was exerted through the colleges of San Pedro y San Pablo (1573) and San Gregorio Magno (1586) in the capital, and through a network of colleges and residences in the center of the country, which were dedicated to raising the cultural, moral, and religious level of the ruling class, both the Spanish-born *Peninsulares* and colonials

of pure Spanish blood (*Criollos*). A group of missions in the northwest sought to save Indian souls while improving their material welfare. Intellectually, the Jesuits contributed to the knowledge of linguistics and other sciences. In 1767 they were expelled by Charles III from all Spanish territory and the order was suppressed by Pope Clement XIV in 1773.

Other Orders.—The Alcantarines (1580) erected the Custodia of San Diego de Alcalá, making it a province in 1599; the Carmelites established themselves in 1585; the Mercedarians, in 1589; and the Benedictines, in 1602.

The Mexican Order of St. Philip installed its first oratory in 1702. Besides these, there were other masculine orders as well as orders for women, such as the Conceptionists (1540), the Dominican nuns (1580), the Poor Clares (1570), and the Capuchin nuns (1704), the Brigittines (1743), and the Company of Mary (1754).

Education.—The clergy was the chief source of education in New Spain. It must be remembered that in the 16th century education was for the upper class. Therefore, in the towns the priests generally taught religion only—since it was felt that the Indian population had no need of other knowledge—but, at times, European trades were taught to Indians in the parishes. Vasco de Quiroga, who was bishop of Michoacán from 1538 to 1565, put into practice an important educational experiment when, inspired by Thomas More's *Utopia,* he organized Michoacán into units, the inhabitants of each unit being instructed in a different trade.

When monastic schools developed, they showed a tendency to turn into universities, but the University of Mexico itself was founded by royal decree in 1551 and opened its doors in 1553. The others that appeared were colleges, with university standing, organized according to medieval ideas.

A great many institutions appeared independently of the university in the 17th century, and were the vehicles for the absorption of the Enlightenment and rationalism, philosophic theories which later inspired the groups that prepared the independence of Mexico.

Press.—The introduction of the printing press in 1535 was a cultural factor of importance. The oldest book known to have been printed by Juan Pablos, owner of the second press brought to New Spain, describes itself as "Short and most complete Christian doctrine in the Mexican and Castilian language, which contains the things most necessary to our holy Catholic Faith, for the profit of the indigenous Indians and the salvation of their souls." This book was published in 1539.

Among the first printers of note (with the dates they were active) were Pedro Balli (1574–1608), Pedro Ocharte (1562–1592), Antonio Espinosa (1558–1576), Diego López Dávalos (1601–1611), and the Calderóns: Bernardo; his wife, Paula Benavides; his son, Antonio Calderón; his father-in-law, Juan de Ribera; and his granddaughter, María de la Rivera Calderón Benavides. Of all those of the viceregal period, the Calderón imprint survived longest (1631–1768). Printing houses were numerous in the 18th century.

In Puebla, the press was first used in 1640; in Oaxaca, in 1720; in Guadalajara, in 1793; and in Veracruz, in 1794. One of the Mexican printing presses, that of Father Juan José Eguiara (d. 1763), had Greek and Hebrew types. A total of some 12,000 works was published in the colonial era.

Newspapers, published as broadsides by the viceroyalty, appeared as early as the 16th century. The first *Gaceta de México* (founded 1667), of irregular publication, was followed by the *Mercurio de México.* The second *Gaceta de México* (1784–1809) was directed by Manuel Valadés. It was replaced in 1810 by the *Gaceta del Gobierno de México.*

Bourbon Era.—The entrance of the Bourbons into Spain (1700), in the person of Philip V, grandson of the French king Louis XIV, greatly changed Spanish thought. Centralism in the French style was emphasized, and rights of autonomy and liberties that might diminish the royal power were rejected. Difficulties with the Jesuits increased until finally, in 1767, they were expelled. The concept of wealth changed, new values being placed on the potentialities of production. Work was honored, science was applied, and social legislation was drafted.

Viceroys.—The first viceroy of the Bourbon kings, Fernando de Alencastre Noroña y Silva, duke of Linares and marquis of Valdefuentes, was in office from 1711 to 1716. First of the great viceroys of the new epoch, his work in collaboration with the tribunal of the *acordada,* which devoted itself to making the highways safe, ended an epidemic of highway robbery that had been a grave problem of the viceroyalty. In the capital he constructed the aqueduct of the Arcos de Belén. He also established cities in the north, and made an excellent study of ecclesiastical and state officials, a frank appraisal of faults, virtues, and procedures, which facilitated the work of later viceroys.

Juan de Acuña, marquis of Casa Fuerte (1722–1734), was called "the Great Governor." He ordered a survey of fortifications in the interior provinces of the north, which extended over four years. In the capital, he constructed the treasury and customhouse buildings.

Antonio María Bucareli y Ursúa (1771–1779) was conspicuous for his personal integrity and administrative ability. As an example of the former, he submitted his luggage to the customs inspection in Mexico City and courteously refused the gift traditionally offered by the city to new viceroys. As an administrator, he succeeded in balancing the budget. Impressed by the fall of Havana to the British in 1762, he organized the defense of New Spain, completing the fortress of San Carlos de Perote near Jalapa, building a fort at Acapulco, and reinforcing the defenses of San Juan de Ulúa at Veracruz. He reorganized the army and collected a gift of 1,299,000 pesos from private individuals to build warships. He established new charitable institutions, started primary schools, and accelerated the teaching of Spanish to the Indians.

Juan Vicente de Güemes Pacheco y Padilla, second Count of Revillagigedo (1789–1794), was an effective administrator who governed with intelligence and strength. He initiated the lighting and paving of the streets of Mexico City.

Transition.—The ideological change introduced by the Bourbons reached the colony in the middle of the 18th century, beginning with the arrival of such capable viceroys as Bucareli and Revillagigedo, who showed genuine concern for the welfare of the colony. In 1786, the French concept of colonial structure brought the subdivision of New Spain into 12 *intendencias,*

headed by officers responsible only to the crown, which strengthened Spanish control over the colony in the face of foreign threats. Despite the abolition of *encomiendas* and *repartimientos,* and the *corregidores* of the Indian towns, many of whom had become miniature despots, social and administrative reforms reached the colony too late to satisfy it.

A spirit of restlessness already prevailed. Viceroy Miguel de la Grúa Talamanca y Branciforte, marquis of Branciforte, who had succeeded Revillagigedo, opposed without success the entrance of the ideology of the French Revolution, and, paradoxically, through exiles from his regime who went to the United States, he prepared the way for the introduction of that country's constitutional ideas into the colony.

Disintegration.—Definite political disintegration arrived in 1808, with the Napoleonic invasion of Spain. As a result of the imprisonment of Charles IV and his son, Ferdinand VII, which raised the problem of sovereignty, the Spaniards in rebellion against the French created municipal juntas (councils) dedicated to the restoration of Ferdinand to the throne. A similar movement took place in Mexico City, where the *ayuntamiento* decreed that in the absence of the king Viceroy José de Iturrigaray was to rule without superior orders.

Taking the opposite view, the members of the *audiencia* (all Spaniards) declared that they represented the will of the populace. Iturrigaray was replaced by Viceroy Pedro de Garibay, and the *audiencia* put itself forward as the representative of the people.

From this issue evolved the first independence movement. Beginning with opposition to French orders and a determination to hold the throne for Ferdinand, it reached a climax with the declaration of absolute independence by the priest Miguel Hidalgo in the town of Dolores, Guanajuato, Sept. 16, 1810.

26. MEXICO FROM 1810 TO 1910. It was in an atmosphere propitious to rebellion that news of the Napoleonic invasion of Spain and the abdications of Charles IV and his son, Ferdinand VII, reached Mexico in 1808. Joseph Bonaparte sat on the Spanish throne, but the Spanish colonies in America refused to recognize him.

In Mexico, the *Criollos,* native-born persons of Spanish ancestry, asserted that sovereignty had devolved on the people, while the *Peninsulares,* persons born in Spain, who feared a movement for independence, supported the juntas (councils) which governed the parts of Spain not occupied by the French. The viceroy, José de Iturrigaray, who for reasons of personal ambition favored the *Criollos,* was seized by a group of wealthy *Peninsulares* on the night of Sept. 15-16, 1808, and replaced by a provisional viceroy, Pedro de Garibay. Nevertheless, the lack of legitimate authorities and the ideological restlessness of the times continued to encourage a revolt.

Garibay was replaced by Archbishop Francisco Javier de Lizana later in the same year, and on Sept. 14, 1810, only two days before the movement for independence was launched by the *Grito de Dolores,* Francisco Javier Venegas, a viceroy sent by the regency formed by the juntas in Spain, took office in Mexico.

Declaration of Independence.—At Querétaro, a modest group of *Criollo* and mestizo intellectuals and military men was preparing a conspiracy. Among them, Miguel Hidalgo (1753–1811), parish priest of Dolores and father of Mexican independence, represented revolutionary thought; Ignacio Allende (1779–1811), captain of the Queen's Regiment, the military. Their attempts to convert others came to the attention of the government and orders were issued for their arrest. Warned in time, by a bold stroke at dawn on Sept. 16, 1810, in the town of Dolores (now Dolores Hidalgo, Guanajuato), Hidalgo proclaimed the independence in the so-called *Grito de* (Cry of) *Dolores.* With the title of general, and leading an improvised army of his Indian parishioners, which grew in size as it advanced, he began a campaign of liberation. The revolt quickly became an uprising of the oppressed masses, dreadful because of the passions it unleashed, and as a consequence the wealthy *Criollos* were driven to support the government. Hidalgo captured Celaya, next the rich city of Guanajuato, and then Valladolid (now Morelia), where he proclaimed the abolition of slavery. The cities of Zacatecas, San Luis Potosí, Guadalajara, and Saltillo were taken by other groups of insurgents.

Hidalgo then continued toward the capital. Nevertheless, after a victory of his ill-organized army, which then numbered about 80,000 men, over some 7,000 Spanish troops at Monte de las Cruces between the valleys of Toluca and Mexico, Oct. 30, 1810, he turned back to Valladolid and finally established his government at Guadalajara. His soldiers now began to leave him.

Felix Calleja, the cleverest and most illustrious of the royal officers, recaptured Guanajuato from Allende, and when the latter joined Hidalgo at Guadalajara, he decisively defeated the insurgent army at the bridge of Calderón on the banks of the Lerma River, Jan. 17, 1811. Hidalgo and Allende escaped toward the north, trying to reach the border of the United States, but were captured at Acatita de Baján, Coahuila, on March 21. Hidalgo was tried and shot at Chihuahua, July 30, 1811.

Morelos.—The first destructive impetus of the insurrection was followed by a desire to justify it. The priest José María Morelos (1765–1815), who continued the movement begun by Hidalgo, is known both for his political and his military activities. Morelos had raised an army of some 9,000 men in what is now the State of Guerrero. Among his able subordinates were Mariano Matamoros (1770?–1814) and Vicente Guerrero (1783–1831). As chief of the insurgent forces, Morelos carried the war into the modern states of Guerrero, Oaxaca, and Morelos, while other insurgents fought in the Central Plateau and other areas.

Calleja was occupied in putting down the insurrection in the north and Michoacán, but early in 1812 he turned south. Morelos resisted him

at the memorable siege of Cuautla, in the modern State of Morelos, March 5-May 2, 1812; then fought his way out. When Calleja returned to the capital, Morelos reoccupied Cuautla and undertook a campaign in east central Mexico, taking Orizaba and other towns west of Veracruz. The meeting of a national congress at Chilpancingo in 1813, which issued a declaration of independence and published the Constitution of Apatzingán, Oct. 22, 1814, was made possible by his zeal and decision.

In February 1813, however, Venegas returned to Spain, and Calleja replaced him as viceroy. The exhaustion of the country now turned more and more people in favor of the government. Morelos was defeated in attempting to capture Valladolid, mainly through the efforts of a royalist officer, Agustín de Iturbide, and again defeated at Puruarán, where Matamoros was captured and later shot. Oaxaca, Cuautla, and Chilpancingo fell to the royalists, and Morelos, heart of the rebellion, was himself captured following a defeat at Tezmalaca, Guerrero, while conducting the national congress to Tehuacán. He was tried and shot at San Cristóbal Ecatepec, near the capital, on Dec. 22, 1815.

With the death of Morelos, the few remaining rebellious groups, led by Guerrero, were restricted to the mountains of the south and Guanajuato.

In 1816 Calleja was replaced as viceroy by Juan de Apodaca, who granted pardons from the Spanish crown to all who would submit, and the new viceroy almost managed to pacify the country. In 1817, only the Spaniard Francisco Javier Mina (1789–1817), a true example of the militant liberal, who had come from Spain to fight for the insurgents in Guanajuato, menaced the peace of the viceroyalty, from April until October, when he too was captured and shot.

Iturbide.—In 1820, at Cádiz, Spain, Gen. Rafael del Riego rebelled against the absolutist regime of Ferdinand VII, and the king was forced to swear to abide by the liberal Constitution of 1812 in order to retain his throne. This political change in the mother country had important repercussions in Mexico. The *Peninsulares* feared the liberal reforms, while the Mexican insurgents saw the possibility of finally reaching an agreement with Spain.

Agustín de Iturbide, former royalist commander in the Bajío region, who in 1820 was appointed to end Vicente Guerrero's rebellion in the south, saw an opportunity of conciliating the dissimilar interests of Mexico's political parties, now tired of the armed struggle. He succeeded in gaining the confidence of Guerrero, the support of the clergy—who feared that the Spanish liberal government would disentail the church properties held in mortmain—and acceptance by the *Criollos*. Iturbide adopted the Plan of Iguala, Feb. 24, 1821, which was agreed to by Guerrero. This was a program of reforms or political changes, also called the Three Guaranties: the independence of Mexico; the union of *Peninsulares* and Americans; and one religion, Catholicism. By the summer of 1821 nearly all Mexico had rallied to the plan.

On July 30, a liberal viceroy, Juan O'Donojú, arrived at Veracruz to succeed Apodaca. Iturbide was fortunate in being able to place his army between the new viceroy and the capital, and obtained his acquiescence to the Plan of Iguala in the Convention of Córdoba, Aug. 24, 1821. Thus after an active military and propaganda campaign, Iturbide's triumphant army entered the capital of the new country on Sept. 27, 1821.

The Captaincy General of Guatemala, comprising Chiapas and the five modern nations between Mexico and Panama, had also declared its independence in 1821 and in the next year was incorporated in Iturbide's empire. Many difficulties were found in annexation, however, and following Iturbide's abdication all but Chiapas separated from Mexico in 1823.

Struggle for Shaping the State.—During the next 36 years the Mexicans were resolutely to seek institutions to change the former colonial political body. Carried away by the promises of political liberalism and the ideals of freedom and equality, in a struggle against reality, they were to experience many disappointments before arriving at the Constitution of 1857.

Which form of government was to inaugurate Mexico's life as an independent nation? Iturbide, backed by the royalists and clergy, favored a constitutional monarchy, since it was believed that the political habits of the country were more in accordance with a monarchy than a republic. The people welcomed the consummation of independence with great enthusiasm, but soon realized that their difficulties were not over and that the situation of their country was difficult and full of danger. The heavy loss in lives and property occasioned by the separation from Spain was forgotten for the moment, but soon poverty, disorder, and unrest again brought the governing groups into conflict.

Spain refused to recognize the Convention of Córdoba, and free trade, the substitute for Spanish commercial policies so anxiously awaited, and in which so much hope had been placed, could not be regularized. An exhausted exchequer and an undisciplined, hungry populace complicated the administrative task.

In hope of bringing order to the nation, the army proclaimed Iturbide emperor on May 18, 1822. Congress was dissolved, and the farce of setting up an imperial court increased the national expenses. Almost immediately, those favoring a popular representative government rose in rebellion; in December, Gen. Antonio López de Santa Anna proclaimed the republic in Veracruz and was joined by many of Mexico's former leaders in the war against Spain, including Guerrero. Iturbide could not curb the new revolution. He abdicated, March 19, 1823, and left for exile. A congressional decree outlawed him if he should return to the country, and when, hoping to regain his prestige and ascendency, he landed at Soto La Marina the next year, this decree was used to condemn him. He was shot at Padilla on July 19, 1824.

Once the monarchy had been discarded, the struggle continued over the question of whether Mexico was to be a federal or a centralized republic. It was believed that federation was a magic formula to bring happiness to the people, but few serious attempts at decentralization were actually carried out. The federal Constitution of Jan. 31, 1824 was the result of temporizations by the liberals, the army, and the clergy. It was in force until 1836, after which there followed in quick succession various experiments in centralized and federal forms of government (see also the section *Government*).

The political parties defined their views under the names of Liberals, who were generally federalists and in favor of reducing the power

of the church; and Conservatives, who were generally centralists, sometimes royalists, and were supported by the great landowners. Freemasons were active politically, those of the Scottish rite enlisting in the Conservative Party; those of the York rite, in the Liberal. Neither party, however, was able to unify the country's opinion and support behind it. In this situation appeared the military *caudillos,* who supported this or that regime according to their preferences.

The first president was a veteran of the struggle for independence, Guadalupe Victoria, who was in office from 1824 to 1829, when following a revolt, Vicente Guerrero was installed. Within a few months Guerrero was overthrown by his vice president, Anastasio Bustamante (1829), and in 1832 the latter was put out of office by Santa Anna, the most prominent of the *caudillos,* who in 1829 at Tampico had received the surrender of King Ferdinand's last attempt to reconquer Mexico.

Santa Anna left the powers of his office to his vice president, Valentín Gómez Farías, under whom took place the so-called Reform of 1833, which separated church and state and provided for secular education. The next year, however, Santa Anna assumed power on behalf of the Conservatives, and the reform was largely nullified. A new constitution (the so-called Seven Constitutional Laws), centralizing the government, was promulgated on Dec. 29, 1836. This, and the activities of settlers from the United States in Texas led to the secession of that province in the same year. Santa Anna was unable to put down the rebellion and retired to his estate in Veracruz.

After a short interim, Bustamante again became president (1837–1841). In 1838 a French fleet attacked and occupied the port of Veracruz with the object of collecting indemnities claimed by its nationals. Santa Anna, who participated in the defense, regained some of his former popularity and was able to make himself president again in 1841–1842. On June 12, 1843 a highly centralized constitution (the so-called Bases Orgánicas) was adopted, and Santa Anna was president under it in 1844. He was overthrown and was succeeded by José Joaquín Herrera (1844–1845). The latter was replaced in 1846 by Mariano Paredes, under whom war began with the United States.

During this chaotic period agriculture was neglected, mining could not be made to prosper, and the incipient industrialization could not be protected. The greater part of the governmental receipts went to the army, which had to be paid to prevent insurrections. The treasury was bolstered by internal and foreign loans which tied up the customs revenues, and the urgent financial needs of succeeding governments made dishonest transactions very easy. This difficult situation was exploited by a group of foreign traders and speculators. Some measure of Mexico's difficulties may be seen in the fact that the country had some 30 changes of chief executives between 1824 and 1848.

The war with the United States in 1846–1848, a conflict which had been maturing since the early years of the century, caught the country in complete prostration. The military campaign showed the Mexicans how disorganized and weak they were. By the Treaty of Guadalupe Hidalgo, Feb. 2, 1848, Mexico was forced to cede half her territory to the United States. (See also MEXICAN WAR; and the section *Relations with the United States.*)

Decisive Decade (1857–1867).—The federalist Constitution of 1824 had been restored following the fall of Paredes in 1846, in an effort to unify the people during the war. After Santa Anna, who had returned to fight, had left the country in 1848, José Joaquín Herrera again became president (1848–1851) and was succeeded, peacefully for the first time in Mexico's history, by Mariano Arista (1851–1853). The latter, however, was driven from office by the Conservatives, who then restored Santa Anna as dictator. But the political problem was now reaching a climax.

In 1855 Santa Anna was overthrown for the last time by a group under the leadership of Juan Álvarez, once a lieutenant of Morelos, and Ignacio Comonfort, with the Plan of Ayutla, March 10, 1854, which called for a federal constitution. The accumulated demands for an end to privilege and oligarchical groups mark the succeeding period as one of social revolution.

While Álvarez was acting president, August to December 1855, his minister of justice, Benito Juárez, abolished the privileges of the army and clergy by means of the Ley (Law) Juárez. Álvarez was then succeeded by Comonfort, whose secretary of the treasury, Miguel Lerdo de Tejada, set forth the Ley Lerdo of 1856, disentailing properties in order to put the holdings of religious communities into circulation. These laws were to be the basis for the economic and political regeneration of the country.

Meanwhile a constituent congress had drafted a new constitution, which was promulgated on Feb. 5, 1857. The principles it proclaimed were considered too bold and too advanced by some, and it was also prejudicial to an important social group, encountering the open opposition of the Conservatives. President Comonfort himself soon turned against the constitution and a Conservative coup was executed in the capital by Gen. Félix Zuloaga. Comonfort's defection began the so-called War of the Reform (1858–1861).

The duty of defending the Liberal institutions fell upon Benito Juárez (1806–1872), as president of the Supreme Court of Justice. His government was pursued by the Conservatives, led by Zuloaga and Gen. Miguel Miramón, until it was established at Veracruz, where Juárez promulgated the Leyes de Reforma (Reform Laws), 1859–1860, as an extreme means of achieving the economic and social policy of the Liberals. These laws included the nationalization of property owned by the church, the establishment of civil marriage, the secularization of cemeteries, the abolition of monastic orders, the separation of church and state, and the establishment of freedom of worship. While Veracruz proved impregnable against Miramón, Santos Degollado and Jesús González Ortega led the Liberal Army to success. After the latter's victory over Miramón in the Battle of Calpulálpam, Dec. 22, 1860, the Liberal troops again occupied the capital, and Juárez was elected president in March 1861.

After this three-year war, the task of reorganizing the country was difficult. Some Conservative groups were still fighting in various regions, and traffic through the country was insecure due to gangs of highway bandits. The expenses of the war and the destruction of national wealth had exhausted the treasury, and

Juárez found it necessary to suspend payment on the public debt (Decree of July 17, 1861).

Encouraged by Mexican Conservatives, France and Spain joined England in a triple alliance (Treaty of London, Oct. 31, 1861) under the pretext of demanding payment of the debt. Napoleon III, however, planned to intervene directly in Mexico, since he could then aid the Confederacy in the Civil War being fought in the United States, and could, furthermore, establish a European prince on the throne of Mexico. When the foreign troops arrived at Veracruz (December 1861 to January 1862), Juárez sent delegates to discuss their differences within the limits of honor. The Spanish and English representatives, Juan Prim and Sir Charles Wyke, recognized Mexico's rights and re-embarked their troops. Only the French failed to come to an agreement and revealed their true intentions by invading the country. The clerical and Conservative group joined them. The French marched toward the capital, but were defeated at Puebla, May 5, 1862, in a famous battle which greatly surprised the foreign countries and covered Mexican arms with glory. As Napoleon III was now compelled to send re-enforcements to conquer the country, his help to the Confederacy was delayed, thus benefiting the Union cause. The re-enforced French soldiers under generals Élie Frédéric Forey and Achille Bazaine defeated the Mexicans, and entered the capital in June 1863. Juárez' government was pursued northward, through San Luis Potosí, Saltillo, and Monterrey, finally reaching Paso del Norte (now Ciudad Juárez).

The so-called Junta de Notables (Assembly of Notables) made up of rich Mexican Conservatives, in agreement with Napoleon III, then offered Archduke Maximilian of Austria a throne in Mexico, assuring him that all Mexicans wanted him for their monarch. This prince renounced his rights in Europe and made burdensome concessions to Napoleon in exchange for his support. He and his wife Carlota still believed that they had been summoned by all Mexico, but were disillusioned by their cold reception in June 1864.

At first, Maximilian had the support of the Conservatives, but as he wished to follow a policy of adjustment and moderation and did not revoke the Reform Laws, he lost their backing and that of the clergy. Nor could the country's rebelliousness be brought to an end; where least expected, groups of patriots would appear.

The enterprise thus became long and expensive for the French. All their hopes for gaining important commercial advantages failed. Following the Union victory in the United States (1865), the Monroe Doctrine was invoked, and Napoleon III abandoned his Mexican adventure in 1866. To keep their throne, Maximilian and Carlota appealed to the courts of Europe, and even tried to come to an agreement with Juárez. The latter obtained the help of the United States and little by little his generals defeated the imperial forces. Maximilian surrendered at Querétaro, May 14, 1867, and on June 19 was shot, to the amazement of Europe.

Republic Restored.—On July 15, 1867, Benito Juárez announced to the nation that the enemy had been defeated, and declared that "among individuals as among nations the respect for the rights of others is peace." Again Juárez was faced with a postwar problem, which meant the liquidation of rebel groups, the enactment of the Constitution of 1857 and the Reform Laws, and the start of a "progressive revolution" that would inaugurate a new era in Mexico.

In the elections of 1867, Juárez defeated one of his generals, Porfirio Díaz (1830–1915), and in those of 1871 he again triumphed over Díaz and Sebastián Lerdo de Tejada (1825–1889). Díaz, dissatisfied with the returns of the election, rebelled with the Plan of La Noria (1871), condemning the re-election of the president. Juárez' prestige proved greater than the armed revolt, but a short time later Juárez died (July 18, 1872). He was succeeded by Sebastián Lerdo de Tejada, president of the Supreme Court of Justice, a man of great talent and a distinguished Liberal, who had followed Juárez during the French intervention. At first, Lerdo's government was very popular. He incorporated the Reform Laws in the constitution and halted railroad construction for fear of United States imperialism. But his intellectual rectitude prevented him from following a policy of conciliation and his somewhat haughty manner made enemies of his former sympathizers. When he announced that he would seek re-election, Díaz revolted, with the Plan of Tuxtepec (1876), again condemning the re-election of the president. After the Battle of Tecoac, in which Gen. Manuel González destroyed Lerdo's forces, Díaz triumphantly entered the capital on Dec. 23, 1876.

Porfirian Era.—Porfirio Díaz promised order and peace. He was a good administrator, a famous officer, and a lover of progress. Upon being elected to the presidency, he inaugurated a long regime that was to change the aspect of the country. Following his first presidential term he entrusted the post to Gen. Manuel González (1880–1884); afterward, he had the constitution reformed so as to re-elect himself indefinitely. In 1904 the office of vice president was created, for which Díaz chose Ramón Corral.

The dictatorship of Díaz welcomed foreign investment, encouraged railroad construction, and entered into commercial treaties; in general, under the direction of Finance Minister José Limantour, it ended the colonial economic regime. It expedited laws for colonization and land surveys, but without effectively benefiting immigration or the protection of agriculture. In mining, the principles of concession and the denunciation of unworked properties were kept. Petroleum, however, was now granted as the property of the owner of the land, a principle which was to have far-reaching consequences in post-Porfirian Mexico. Industry prospered, principally with English capital, and material improvements, such as the construction of harbors, canals, and buildings, were of great importance.

Education was carried forward in secular institutions through application of the Law of Public Instruction of 1867, which was based on the doctrines of French positivism. Toward the end of the Díaz regime ambitious cultural works were undertaken, existing facilities, such as the National Library and the National Museum, were improved, and numerous writers and poets contributed to the Europeanization of Porfirian culture.

The material progress of the country was evident, but the dictatorship nullified political progress, and the creation of a new wealthy class postponed the solution of the social problem. The work of progress did not reach the immense Indian population, living in poverty

and debt peonage in the fields. Great numbers of the communal lands (*ejidos*) owned by Indian villages had been alienated, and the ownership of land had been concentrated in fewer and fewer hands.

General Díaz and his ministers grew old in power, opposition increased, and the disorder that the dictator's death might bring was feared. A vice president more popular than Corral was wanted. This was one of the themes of a notable book of the time, *La sucesión presidencial en 1910* (1908), written by a member of a wealthy family of Coahuila, Francisco Madero (1873–1913). Madero, representing the popular restlessness, ran for election in 1910, but Díaz reelected himself, again naming Ramón Corral as vice president. On Nov. 20, 1910, Madero revolted, inaugurating the overthrow of the regime.

Professor of History, Universidad Nacional de México.

27. MODERN MEXICO. Outbreak of the Revolution.—Francisco Madero pointed out his reasons for beginning the armed movement against the Díaz regime in his Plan of San Luis Potosí (dated Oct. 5, 1910): an intolerable tyranny in exchange for a shameful peace imposed by force, which had favored only a few; a complete contempt of the country's constitution; a mercenary justice; a congress at the dictator's orders; everything arranged so that Díaz could maintain himself in power. This political retrogression had produced a deep ill feeling in the country, intensified in 1910 with the naming of Ramón Corral to the vice presidency. On the social side, there was the problem of the land and the peons.

Madero's party adopted the slogan, "Sufragio Efectivo, No Reelección" (Effective Suffrage, No Re-election). Their leader declared that he had entered the political struggle honestly and would have been elected president but for electoral frauds. In so doing he put himself at the head of all the Mexicans who wanted to protest with guns in their hands against the illegality of the elections and the violation of the national will.

The revolution thus began spread rapidly. In Santa Clara, Puebla, Aquiles Serdán proclaimed the revolt in November 1910, but was killed almost immediately. At about the same time Pascual Orozco proclaimed it in Ciudad Guerrero, Chihuahua. The revolt in the north was joined by Francisco Villa. In March 1911 Emiliano Zapata rose in rebellion in Morelos, demanding land and better living conditions for the peons.

The Federal Army, commanded by Díaz' generals, could not contain the uprisings. On May 21, 1911 an armistice was signed between the Federal forces and the revolutionaries. Díaz sent a delegate to sign an agreement with the rebels, then renounced the presidency, May 25. The secretary of foreign affairs, Francisco León de la Barra, was named provisional president. In special elections, in October 1911, Francisco Madero was elected president and was sworn into office on November 6.

Madero had been elected with the strictest legality—but there were other questions besides that of democratic suffrage. The new president came to terms with the moneyed classes and other influential groups of the Porfirian regime, and thus the social, economic, and religious questions were left unsolved, and the revolutionary groups remained in arms.

The Zapata revolutionaries in Morelos, dissatisfied because Madero had not carried further the revolution begun with such success, protested energetically in the Plan of Ayala of Nov. 25, 1911. Their slogan was "Tierra y Libertad" (Land and Liberty), and it proposed the complete destruction of the Porfirian system and an agrarian reform. Pascual Orozco rebelled against Madero in March 1912, but was driven out of Mexico by Gen. Victoriano Huerta. Bernardo Reyes attempted to revolt in Nuevo León, and Félix Díaz, a nephew of the former dictator, rose in Veracruz, but these also were put down.

The delicate international situation was another of Madero's problems. The United States remained vigilant, watching events, especially along the border, but its ambassador, Henry Lane Wilson, favored active military intervention against Madero's government. In April 1912, Wilson entered a claim for damages for injury to lives and properties of American citizens resulting from the revolutionary fighting, and he did everything in his power to cause the intervention of his country in the internal affairs of Mexico.

On Feb. 9, 1913, Félix Díaz and General Reyes, who had been imprisoned in the capital, were freed by troops who had rebelled against Madero. Reyes was killed, but Díaz and the rebels took refuge in the Ciudadela (Citadel). There followed ten days of uncertainty, intrigue, and fighting in the city, known as the "Tragic Ten Days." Madero's commander, Huerta, taking advantage of the bloody fighting, arrested the president and Vice President José María Pino Suárez on February 18, obtained their resignations, and on February 22 had them shot while they were being transported from the National Palace to the penitentiary. The usurper Victoriano Huerta, supported by Ambassador Wilson and the reactionary Porfirian group, then took over the presidency. His government was recognized by Great Britain and several other countries, but not by the United States.

Carranza.—Huerta's treason angered the governor of Coahuila, Venustiano Carranza, who was to be the organizer of the revolution, as well as Zapata, Villa, and other revolutionaries. Supported by numerous military leaders, Carranza launched the Plan of Guadalupe of March 26, 1913, disowning the government of Huerta. The latter lost Wilson's backing when the ambassador resigned his post following the election of President Wilson in the United States.

On April 9, 1914, some United States sailors landed in Tampico in search of provisions. They were arrested by Mexican soldiers and later released upon proving their nationality. This incident provoked an exchange of notes between Mexico and the United States. Huerta adopted

a provocative attitude, the result of which was that the new government of the United States broke off relations with his government and in February lifted the arms embargo to authorize the sending of munitions to the usurper's enemies. Later, it ordered United States marines to land in Veracruz (April 21, 1914). This intervention and invasion caused an energetic patriotic reaction in Mexico.

Meanwhile other revolutionary groups had joined Carranza, declaring him chief of the Constitutionalist Army. In March 1914 they attacked the city of Torreón, and their capture of Zacatecas in June was the decisive blow against Huerta's forces. From there, Gen. Alvaro Obregón of the Constitutionalist Army advanced to Teoloyucan, near Mexico City, where the rest of the Federal Army surrendered. Huerta abandoned the capital on July 15, 1914, and went into exile. When Carranza entered Mexico City in August, he had to face the difficulties with the United States. Since these had concerned the usurping government, he demanded that the United States forces leave Veracruz, and the port was evacuated in November 1914.

Villa, who enjoyed great popularity in the north, and Zapata, who was fighting for his ideals in the south, had been unwilling to recognize Carranza's leadership, since it seemed to them that he was interested only in the political part of the revolution, rather than its social and economic causes. The partisans of Villa and Carranza thereupon decided to call a convention to agree on a plan of future reforms. The convention met briefly in Mexico City, and later at Aguascalientes, a neutral city, in October 1914, but Villa, distrustful of Carranza, then disowned his authority and marched on Mexico City.

Carranza was obliged to leave the capital for Veracruz; nevertheless, this port city was a more favorable location, since it was beyond reach of his enemies, and the customs duties provided funds. In Veracruz, Carranza began to organize the revolutionary government, and initiated the agrarian reform with the law of Jan. 6, 1915. Meanwhile, his generals were fighting the partisans of Villa and Zapata. These groups attempted to establish a national government in the capital, and discussed social and agrarian reform at sessions of the Supreme Revolutionary Convention. They were driven from Mexico City in January 1915, however, and Alvaro Obregón decisively defeated Villa in the Battle of Celaya in March, forcing him to retreat to the north. The Supreme Revolutionary Convention, subjected to the hazards of war, finally took refuge in Morelos, where it was dissolved when Carranza's troops marched in. Zapata continued his resistance until he was killed in 1919.

The United States recognized the government of Carranza in October 1915. Frustrated in his ambitions, and unable to obtain arms from the United States on account of this recognition, Villa had a group of United States citizens shot in January 1916 and on March 9 attacked the town of Columbus, New Mexico. The United States then sent Gen. John Pershing on a punitive expedition. Carranza ordered the defense of Mexican territory, thus creating a very difficult situation. Nor would he enter into any agreement as long as United States troops remained in Mexico. When, in February 1917, the troops finally left the country, the two governments had not reached an agreement, and Pershing's troops had not been able to capture Villa.

In order to restore constitutional methods in Mexico, Carranza called elections, in September 1916, for a constituent congress, thus fulfilling promises made in the Plan of Guadalupe and providing for the incorporation of revolutionary legislation in the Constitution of 1857. This congress met in the city of Querétaro from Dec. 1, 1916 to Jan. 31, 1917, and formulated a new constitution, which was promulgated on Feb. 5, 1917. Once the triumph of the Constitutionalist forces had been consolidated, Carranza called special elections for president, representatives (*diputados*), and senators; being himself elected president of the republic.

The Constitution of 1917 established a representative, democratic, federal republic. Some of its articles represent very advanced social tendencies, as well as the outlines for a national utilization of the national wealth. Articles 5, 27, 123, and 130 are especially important because of the reforms they envisaged and because of their consequences in national and international politics.

Article 5 established the principle that no one may be forced to render personal services without just compensation and without his full consent. Article 130 undertakes the difficult problem of relations between the state and the church, and grants the federal authorities the right to oversee religious worship and the relations between the church and the people. Article 27 is the basis of the agrarian reform and of regulations for the exploitation of the subsoil. Article 123 refers to labor and social planning, and establishes the basis for labor contracts. (Details of Articles 27 and 123 are given in the section *Economic, Agricultural, Industrial, and Financial Factors*—Modern Economic Policy).

The history of Mexico after 1917 may be viewed as an effort to carry out the principles and lines of policy laid down by this constitution. The effort has not always been constant and sustained. Often violated by personal ambition, foreign pressure, or the avarice of various social groups, it has nevertheless triumphed over other social and political policies which have been proposed for the country.

One of Carranza's measures was his decree of Feb. 19, 1918, declaring Mexican petroleum to be an inalienable national resource and beginning a long struggle to bring petroleum under Mexican control.

Post-Revolutionary Governments. — Carranza attempted to impose Ignacio Bonillas as his successor in the elections of 1920, but Alvaro Obregón, a leader of Carranza's partisans, used the old procedure of seizing power by armed force. He rose with the Plan of Agua Prieta (April 23, 1920) in defense of popular suffrage, and was joined by others of the military, notably generals Plutarco Elías Calles and Adolfo de la Huerta. Carranza, fleeing from the capital, was murdered at Tlaxcalantongo, Puebla, May 21, 1920. De la Huerta then became provisional president, and the remnants of other anti-Carranza forces abandoned the struggle. On July 27, 1920, Villa, who had maintained a futile opposition in the north, surrendered to the new government. The few followers of Zapata who had remained in arms in Morelos also came to terms.

Obregón was elected president on September 5, and took office on Dec. 1, 1920.

Obregón.—Prosperity increased under Obregón, and labor unions flourished, particularly the Confederación Regional de Obreros Mexicanos, which had been organized in 1918. Obregón's administration also marks the beginning of modern Mexican education, in the hands of José Vasconcelos, secretary of public education from 1921 to 1924. Elementary education was increased, and literacy campaigns and school-building programs were undertaken. Rural instruction carried a hope of social change through education to the most distant villages. (See also the article *Education.*)

With the encouragement of Vasconcelos there also arose from the revolutionary movement an art expressing the drama of the Mexican people. Diego Rivera, José Clemente Orozco, and David Alfaro Siqueiros, at the head of many others, have shown the world the problems of modern Mexico.

During 1923, Obregón antagonized the clergy when he expelled the apostolic delegate for transgressing the laws. Catholics openly objected to this measure, but the real conflict was delayed until the administration of Calles, to whom Obregón left the presidency at the end of his term in 1924, but not without having overcome a revolt by de la Huerta in 1923–1924.

Calles.—Under the new administration prosperity continued, and the labor movement attracted increasing numbers of workers. The fiscal system was put on a sound basis in 1925, when nonproductive taxes were abolished and government income was increased by the levy of an income tax. The Banco de México was also founded in that year. Due to programs of material improvement, dating from Calles' administration and thereafter, means of transportation and communication have brought towns and villages which had been isolated for centuries into contact with the rest of the country, and schools, public buildings, and hospitals have changed the colonial or Porfirian appearance of many cities.

In 1925–1926 the Congress passed laws enforcing the provisions of the Constitution of 1917 in regard to foreign-owned land and Mexican mineral resources. This led to a diplomatic conflict with the United States, which alleged that the laws were confiscatory. The dispute was settled in 1927, but the Mexican goverment did not retreat from its stand on any of the basic questions.

In February 1927 the church publicly repudiated the Constitution of 1917. Calles faced the ensuing conflict by putting the anticlerical measures of 1917 into effect. Ecclesiastical property was nationalized and foreign priests and the archbishop were expelled, together with other prelates. In October the so-called *Cristeros* rose in arms to fight for *Cristo Rey* (Christ the King). The revolt was centered in Jalisco and Guanajuato; there, and in other states there were bloody persecutions and reprisals.

At the end of Calles' term, the constitutional provision against re-election was set aside, and Obregón ran again. He was re-elected, but before taking office was assassinated, July 17, 1928, by the Catholic fanatic León Toral. A lawyer, Emilio Portes Gil, was elected by Congress as provisional president.

Portes Gil.—Relations between the government and the church became more conciliatory in 1929. The provisional presidency of Portes Gil is also noteworthy for the foundation by Calles in March 1929 of the political party successively called Partido Nacional Revolucionario, Partido de la Revolución Mexicana, and Partido Revolucionario Institucional, an intimate part of the government, and the party to which all presidents after Portes Gil belonged. Its first nominee, Pascual Ortiz Rubio, defeated José Vasconcelos in special elections held in 1929.

Ortiz Rubio and Rodríguez.—After the new president had taken office, Mexico entered the worst of the world depression. The economic situation and a conflict within his administration, in which he was opposed by Calles, led to the president's resignation, Sept. 3, 1932. Gen. Abelardo Rodríguez was elected by Congress to fill out the remainder of the term. The Nacional Financiera, an institution of great importance, through which the government later promoted many industries of special utility to the nation, was founded in 1933.

Cárdenas.—In 1934 Lázaro Cárdenas was elected to a six-year term, in accordance with a constitutional reform of April 29, 1933. Social legislation, agrarian reform, and economic development received a new impetus from Cárdenas, who represented the more liberal wing of the official party. The president came into conflict with Calles in 1935 and in the next year Calles was deported.

An important pillar of the Cárdenas regime was the Confederación de Trabajadores Mexicanos, a new labor organization founded in 1936 in opposition to the older C.R.O.M. and led by Vicente Lombardo Toledano. The circle of the official party was widened in 1938 to include workers and peasants, in order to bring them into participation in the political and economic direction of the country.

In 1936, when Cárdenas decided to reform Article 3 of the constitution, dealing with education, the religious situation again became critical, but relations between church and state thereafter were improved, due less to changes in legislation than to a conciliatory attitude on the part of the government. (See also the article *Church and State.*)

A major objective of the Cárdenas administration was agrarian reform. To this end the distribution of lands, which had been somewhat in abeyance, was increased, and various institutions through which farmers could obtain credit were established.

A significant development took place in 1938, when the government completed the long-standing effort to bring Mexican petroleum resources under national control by expropriating foreign-owned oil companies. (Details are given in the section on *Economic, Industrial, Agricultural, and Financial Factors.*) This important move aroused great popular enthusiasm in Mexico and led to a diplomatic controversy with Great Britain and the United States, which was finally settled after an agreement for indemnifying the owners had been reached in 1944.

Ávila Camacho.—In the elections of 1940, Gen. Manuel Ávila Camacho was victorious over Gen. Juan Andreu Almazán. The new administration was notable for an increasing rate of industrialization and the entrance into Mexico of large amounts of refugee capital from Europe during World War II. The government severed diplomatic relations with Japan on Dec. 8, 1941,

a day after the attack on Pearl Harbor, and with Germany and Italy on December 11. War against all three Axis powers was declared on May 28, 1942. Mexico became a member of the United Nations on Nov. 7, 1947.

Alemán.—Miguel Alemán, a lawyer, succeeded Ávila Camacho in 1946. Mexican industrialization rose sharply in the postwar period and Mexican capital became more and more evident in new industries. In 1952 Alemán was succeeded by a new president, also a civilian, Adolfo Ruiz Cortines.

28. RELATIONS WITH THE UNITED STATES. Early Relations and Border Problems.—The independence of Latin America early in the 19th century forced England and the United States into a new field of rivalry. The English, who had traded illegally with the Spanish colonies, signed treaties of friendship, commerce, and navigation with them after their declarations of independence. For its part, the United States felt the threat of European influence to its interests in the Western Hemisphere.

During its colonial past, New Spain (Mexico) had had border friction with its northern neighbor. This was intensified by the vague borders of the Louisiana Territory, sold by the French to the United States in 1803, after being acquired from Spain. The Spanish authorities considered the Mississippi River as the limit of the territory, while the United States insisted on the Rio Grande. The discussion lasted several years, and was ended by the Adams-Onís Treaty of Feb. 22, 1819, under the terms of which Spanish claims in Florida were exchanged with the United States for its claims to the territory lying between the Rio Grande and the Sabine River. This treaty established the boundary line as follows: from the Gulf of Mexico at the mouth of the Sabine River, north along the west bank of the Sabine to latitude 32°N.; due north from this point to the Red River; west along the Red to longitude 100°W.; north along this meridian to the Arkansas River; west along the southern bank of the Arkansas to its source; due north from this point to latitude 42°N.; and west along this line to the Pacific.

The Treaty of 1819, however, had been arranged between the United States and Spain, not with Mexico, which in 1821 became independent. Thus, the new republic inherited the problem. Mexico also inherited the problems of colonizing its frontier territories and of conducting trade with the United States. This trade went between Santa Fe, then in northern Mexico, and the area centering around St. Louis, and was complicated by numberless smuggling and hunting expeditions which violated the border in both directions.

A further troublesome inheritance was the threat of United States expansion westward and southward, one reason for which was the plantation economy of the southern United States, with its dependence on slave labor and large expanses of agricultural territory. Southern desire to extend its way of life into new territories, to counterbalance the extension of nonslave territory in the North, influenced United States policy along its borders with Mexico, and naturally aroused Mexican suspicion and resistance. United States insistence on the need for new land in the southwest seemed all the less reasonable to Mexico because of the still huge undeveloped areas in the western United States.

England, shrewdly realizing that it was in a position to develop commercial relations with Mexico without becoming involved in political or territorial disagreements, improved its position in proportion as Mexican-United States relations deteriorated. The most significant reflection of United States concern over the position it felt England was attaining was contained in the declaration of the Monroe Doctrine of Dec. 2, 1823, calling a halt to European expansion in the Western Hemisphere. Although directed chiefly against Spain and Russia, the doctrine was also an effort by the United States to accomplish in the field of politics what it could not at the time accomplish in the field of trade. Pending the time when it could compete with the trade of Europe, particularly that of England, the United States wished to keep the Latin American market as open as possible. Attainment of the necessary commercial vigor and a sufficiently expanding economy to develop this market fully did not come until after the Civil War.

Indian tribes, frontiersmen, and traders moved back and forth across the border, and such American colonizers as Stephen Austin settled in Texas (in 1821) on Mexican territory. Mexico made efforts to define her frontiers in conformity with the Adams-Onís Treaty of 1819, but the United States refused to acknowledge that the treaty was valid with Mexico unless further border modifications were made.

In the time of Iturbide's empire (1822–1823), immediately after independence, Mexico attempted to win full *de jure* recognition of her government by the United States. Iturbide sent Manuel Zozaya, with full diplomatic powers, as first Mexican minister to Washington. Since in spite of this, between 1822 and 1825 no treaty was ratified between Mexico and the United States, and in light of the expansionism of the latter country, the original Mexican good feeling turned against her northern neighbor. "In time," wrote Zozaya of the United States, "they will be our sworn enemies, and foreseeing this we should treat them as such from the present day." Zozaya's viewpoint shaped the Mexican attitude.

Under the Constitution of 1824, Mexico became a federal republic. Joel Roberts Poinsett was sent as the first American minister in 1825. Poinsett seemed to have real qualifications for the position, but most of his recommendations were rejected by Mexico. He proposed construction of a new road between Santa Fe and St. Louis to make possible the passage of wagon trains, a treaty which would recognize the borders of the Treaty of 1819, and a "most favored nation" tariff agreement between the two nations. Yielding to Mexican opposition to these plans, however, he accepted the Mexican terms and in January 1826 signed a treaty of friendship, trade, and navigation, by which Mexico was recognized by the United States, but which bypassed a settlement of the frontier question.

The situation remained static until the end of Poinsett's mission in 1829, despite his government's insistence on frontier changes, because the Mexican government recalled Zozaya's warning and it seemed that any change in the position of the border would set a dangerous precedent. As a result, the United States refused to ratify the Treaty of 1819 on borders and Mexico did not ratify Poinsett's treaty of friendship, trade, and navigation.

Poinsett's efforts to exert political influence in Mexico in order to obtain the privileges desired by the United States, since the volume of trade with his country was not sufficient to impose its conditions, were sharply criticized by the Mexicans and led to disputes between Poinsett and the British minister, Henry George Ward. When Poinsett assisted in the formation of a lodge of York Rite Freemasons, which promptly became a Mexican political party (the *Yorkinos*), he aroused so much enmity that he was forced to leave the country. After his departure, bad feeling was further aggravated, at times because of lack of tact on the part of succeeding ministers, who insisted on border changes, and by violations of the Mexican border and abuses of Mexican custom officials.

Texas Question and Mexican War.—Above all, bad feeling was created by the part played by the United States in Texan independence, the basis of which was the effort of the Southern states to expand slave territory. The constant and often violent changes of government in Mexico did not help matters, and the anarchy which frequently prevailed encouraged American diplomatic representatives to seek settlement of the frontier question by influencing Mexican government officials. Anthony Butler, who was United States minister from October 1829 to January 1836, for example, tried to obtain the cession of Texas by strategically distributing 100,000 pesos among government officials. Butler suggested extending the southwestern border of the United States all the way to the Pacific, arguing that this was necessary so that a fishing industry could be established in the vicinity of San Francisco and transcontinental communications facilitated.

When Texas, defying the Mexican government, proclaimed its independence in 1836, Mexico tried to reconquer it. The campaign of reconquest was led by Gen. Antonio López Santa Anna, who won the Battle of the Alamo (March 6, 1836) but lost the decisive Battle of San Jacinto (April 21, 1836).

With the independence of Texas, which claimed the Rio Grande as its southern boundary, established by force but not legally recognized by Mexico, Mexican-United States relations were placed under an increased strain. The United States recognized Texas as a new nation in 1837, and other nations followed its lead in granting recognition. Mexico nevertheless continued to insist on its sovereignty over Texas and considered as unfriendly any intervention between itself and its rebellious state.

The problem came to a head in November 1844 after a heated discussion in Mexico City between José María Bocanegra and Manuel Crescencio Rejón for Mexico, and Benjamin Edwards Green and Wilson Shannon for the United States. Rejón analyzed the policies of the United States and charged that its preconceived objective had been to obtain Texas. In January 1845 he said that annexation of Texas by the United States would be considered as a declaration of war against Mexico. Despite this serious position, Mexico was unable to mobilize because of the anarchy and confusion reigning at the time.

The Texas question, as it involved Mexico and the United States, was approaching a climax. Diplomatic relations were broken off in January 1846 and Mexico stopped payment on claims that, despite the work of two arbitration conventions (1839 and 1843), were still pending.

When war came in May 1846, the United States based its declaration of war on the claim that Mexico had begun hostilities by invading United States territory (that is, territory north of the Rio Grande previously claimed by Texas), and "shedding American blood." Mexico, however, denied any invasion and based its stand on the question of Texas. The war is still a matter of great controversy, but at the time many persons in the United States felt it unjustified, and two later presidents, Lincoln and Grant, publicly deplored the action of their country.

Because of internal weakness, Mexico was not able to oppose the United States armies effectively, but spectacular battles were fought (see MEXICAN WAR).

Final peace, sealed by the Treaty of Guadalupe Hidalgo (Feb. 2, 1848), was signed on behalf of the United States by Nicholas Philip Trist, who disregarded his instructions to accept terms regarded by some in the United States as too lenient. Through the treaty, however, Mexico lost half of her territory, including New Mexico, Arizona, all of Upper California, and parts of what are now other states. This treaty established a new boundary line as follows: from the Gulf of Mexico three leagues from land opposite the mouth of the Rio Grande, following the middle of that river to the southern boundary of New Mexico; thence west along that boundary to its western end; north along the western boundary of New Mexico to the first branch of the Gila River; west along the middle of that branch and the middle of the Gila to its junction with the Colorado; thence west along the division between Upper and Lower California to the Pacific Ocean.

Gadsden Purchase.—The peace treaty of 1848 did not solve the problems between the two countries, and the actual position of the southern boundary of New Mexico remained in dispute until the Gadsden Purchase. The southwest border of the United States still was not drawn far enough south to satisfy the promoters of a coast-to-coast railroad, who feared having their trains run too close to the border. Indians from the United States continued to attack Mexican territory and the responsibility of checking them, accepted by the United States in Article 11 of the Treaty of Guadalupe Hidalgo, proved so heavy that that government tried to revoke the clause. Projects for building a canal or railroad across the Isthmus of Tehuantepec were also pending, and were further complicated by concessions made by the Mexican government to individuals, who in turn passed them on to British subjects.

Still desiring more territory, the United States took advantage of the Mexican government's chronic need for money to negotiate the Gadsden Purchase (Treaty of Mesilla) of Dec. 30, 1853, by which Article 11 of the previous treaty was abrogated, the border moved to its present position (for which see UNITED STATES—*Area and*

Boundaries), and the building of the Southern Pacific Railroad was made possible.

Relations with the United States After 1853.—A few years later, the United States fought its Civil War, emerging from the struggle in 1865 with an economic, political, and social structure based on an industrial system which had been ripening in the North and which demanded foreign markets and new fields for investment of capital. Confirmation of industrialism as the national pattern was quickly reflected in United States foreign policy.

During the Civil War, the French invasion of Mexico had installed Maximilian as emperor (1864–1867), in defiance of the Monroe Doctrine. The end of the Civil War, and Mexican resistance led by Benito Juárez, ended the French experiment and Maximilian's life. The re-established Mexican republic received United States support.

During the prolonged presidency (1876–1880 and 1884–1911) of Porfirio Díaz, development of United States industrialization fitted in with material betterment in Mexico, and United States as well as European capital flowed into the country. Through investments, and indirect political influence designed to protect its investors, the United States gained considerable control over the Mexican economy during the Porfirian era. But the material progress made under Díaz was not matched by proportionate social progress, and eventually this pressure produced the Revolution of 1910 and the overthrow of the regime.

The United States began to become aware of the social and economic problems that foreign investment brought to Mexico, and modified its policies so that, despite such incidents during the revolution as the bombardment and occupation of Veracruz by United States Marines in 1914 and Francisco Villa's raid on Columbus, N. M., in 1916, relations were improved.

After the revolution, the most important in Mexico's history, nationalism increased, some foreign properties were expropriated, and foreign investments in major industries were limited.

Then came the era of the Good Neighbor policy, inaugurated in 1933, with hope for understanding based on something more than merely material concerns, and even the acceptance by the United States of the principle that Mexico was entitled to limit economic penetration by foreign capital. (See section *Economic, Industrial, Agricultural, and Financial Factors.*)

Efforts toward mutual understanding seem to have smoothed out the major causes of friction, and *rapprochement* has been strengthened by intellectual movements which began in various universities, and extended through private scientific institutions which have financed exchange students, researchers, and teachers, who contribute to the cause by studying each other's country.

MEXICO, mĕk'sĭ-kō (Span. mĕ'hĕ-kô), state of the Republic of Mexico. Located in the south central section, it is the central portion of a plateau rising 8,000 feet above sea level. Running from northwest to southeast through the center of the state is a range of well-wooded mountains which separate the Valley of Mexico from a second plateau area in which is located the state capital, Toluca.

The state is one of the richest in the republic. Agriculture and mining are equally well developed and there is an increasing amount of industry. Cereals, sugar, the maguey cactus, fruit, dairy products, and livestock are the main products of agriculture, while silver, gold, copper and lead are mined in quantity. Manufactures are concentrated mainly in the area immediately north of the Federal District, an expansion of industries from Mexico City. Cotton and woolen goods, fibers, paper, flour, glass, pottery and bricks, wines and spirits, and metal products are produced. The area of the state is 8,286 square miles; pop. (1950 preliminary) 1,392,623, of which 73.6 per cent was rural.

MEXICO, city, Missouri, seat of Audrain County, is located on Salt River, 25 miles northeast of Columbia, on the Wabash, the Gulf, Mobile and Ohio and the Burlington Route railroads. It is in a farming area raising grains and soybeans, and is noted as a mule market and horse breeding center. There are large deposits of fine fire clay in the county, and the city's manufactured products include fire brick, stove linings, flour, shoes, and soybean products. Missouri Military Academy is here. The city was settled in 1833, incorporated in 1862, and has a council-manager form of government. Pop. (1950) 11,623.

MEXICO, Federal District of (Span. Distrito Federal), area, Republic of Mexico, which is set aside for the exclusive use of the federal government, so that government will not be hampered by state interference. In this it is like the District of Columbia in the United States. The Federal District was created in 1824. The State of Mexico, of which it was formerly a part, bounds it on the east, north, and west; on the south it is bounded by Morelos.

It is the southeastern portion of the Valley of Mexico, and contains Mexico City, the national capital, which is also the capital of the Federal District. The district is smaller than any of the Mexican states or territories, but has a greater population. In 1950 only 5.43 per cent of the population was rural. The most important manufactures are concentrated in Mexico City and its suburbs. Area 573 square miles; pop. (1950 preliminary) 3,062,205. See also Mexico City.

MEXICO, Gulf of, an arm of the Atlantic Ocean, bounded on the north by the United States and on the south and west by Mexico. It is oval in form; its greatest length is, from east to west, about 1,000 miles; from north to south, about 800 miles; area about 716,000 square miles. It has a continuous coastline of about 3,000 miles. Its maximum depth (Sigsbee Deep) is about 12,425 feet, and the average depth is about 4,700 feet. The outlet of the gulf is on the east, between the peninsulas of Yucatán and Florida, a distance of about 475 miles. In this outlet is the island of Cuba, which is separated from Florida by the Straits of Florida, 110 miles wide, and from Yucatán by the Yucatán Channel, 120 miles wide.

The Yucatán Channel opens into the Caribbean Sea, and the Straits of Florida into the Atlantic.

The temperature of the gulf is from eight degrees to nine degrees higher than in the Atlantic in the same latitude. The temperature at the point of greatest depth is 39½°. The range of the tides is small: from about two and a half feet at the neap tides to about four feet in the spring. The chief current is a branch of the Equatorial Current which enters the gulf through the Yucatán Channel, circles the interior, and exits through the Straits of Florida to form the beginning of the Gulf Stream. The winds are about as on other parts of the globe where north-equatorial conditions exist; the prevailing winds from the north blow from September to March, and from the south from March to September. The severe gales are in the winter, and hurricanes may be encountered in late summer or early autumn.

The northern part of the gulf, from Mexico to Florida, is really a coastal plain averaging from 40 to 100 miles wide. The basin off the Mexican coast sinks rapidly to the submarine plain, and a short distance from shore reaches the maximum depth. The Bay of Campeche is the largest indentation.

The chief ports are Havana, Cuba; Veracruz and Tampico, Mexico; and Galveston, Houston, Port Arthur, Beaumont, New Orleans, Mobile, and Tampa, in the United States.

MEXICO CITY (known to the Mexicans simply as "México," mĕ'hĕ-kō), city, capital of the Republic of Mexico. At the time of the census of 1950 it was the second most populous city of the Spanish-speaking world, exceeded only by Buenos Aires, and was the third most populous city in North America, exceeded by New York and Chicago. At the beginning of the 19th century Mexico City was the largest city in the Western Hemisphere. Today it is the political, commercial, financial, and cultural center of the republic, indeed, the focus of every line of national activity.

Mexico City is situated in latitude 19° 26′ 5″ N., 99° 6′ 45″ W. from Greenwich, at an altitude of 7,415 feet above the level of the sea, near the center of the Valley of Mexico and in the political subdivision of the republic known as the Federal District. The climate of the city is mild. The temperature ranges from 35° to 90° Fahrenheit, but the annual average range is from 54° to 65°, the average being 60°. The nights and mornings are cool throughout the year, the hottest months being April and May, which are followed by the rainy season, late May to early October. The average annual rainfall is 23.4 inches, of which an average of 17.8 inches falls from June through September.

The capital is connected with most other Mexican cities by highway or railroad, and with all important ones by air. It is connected with the United States by air, three railroad lines (to Laredo and El Paso, Texas, and Nogales, Arizona), and several highway routes, and with Guatemala by the same three forms of transportation. Mexico City's chief port is Veracruz, some 200 miles east-southeast on the gulf, with which it has rail, highway, and air connections.

Streets, Parks, and Public Buildings.—The streets of the older part of the city, laid out by the Spaniards on a gridiron pattern, are straight, running north and south, and east and west, and intersecting at right angles. In the newer portions, chiefly west and southwest of the old city, there are some diagonal avenues, but the gridiron pattern has generally been maintained, although the north-south orientation is not always followed. The principal avenues and streets are broad, paved with asphalt, and bordered with good sidewalks; many of the streets in the older section are narrow.

The principal square is the Zócalo or Plaza Mayor (officially, the Plaza de la Constitución), situated in the center of the old city. It covers 14 acres, but is only part of the ground enclosed by the walls of the *teocalli* (main temple) of the ancient Aztec city of Tenochtitlan. The entire eastern side of the plaza is bounded by the Palacio Nacional (National Palace), which is said to occupy the site of Montezuma's new palace. The present building was begun in 1692 and has been added to from time to time until now it has a frontage of 675 feet. It is two stories high, long, low, and plain. Originally it was the residence of the Spanish viceroys, but for many years has been devoted to housing some of the executive departments of the national government, including the president's offices.

Over the main entrance hangs the Liberty Bell, with which, in his church at Dolores, the father of Mexican independence, the priest Miguel Hidalgo, called his people to arms on Sept. 16, 1810. It was moved to its present location in 1896, and since then, a feature of every celebration of the anniversary of independence is the ringing of this bell by the president. On the north side of the Zócalo is the cathedral, the city's chief architectural feature, its most majestic, most imposing colonial edifice. The walls are gray stone. From the sides of the façade rise two bell towers 203 feet in height, which command a superb view of the city and the surrounding valley. The cornerstone was laid in 1573; the walls were finished in 1615, and the roof completed in 1623, when the first Mass was said. It was dedicated in 1667, but was not entirely finished until 1791. It occupies an area of 374 by 198 feet and is of composite architecture, blending the Corinthian, Doric, and Ionic.

The interior contains some exquisite wood carving, and some excellent paintings. In this cathedral in 1822 Agustín de Iturbide was crowned emperor of Mexico, and here he is buried, his coffin bearing simply these words: "The Liberator." Here, too, in 1864 the Austrian Archduke Maximilian and his wife Carlota were crowned emperor and empress of Mexico.

Adjoining the National Palace on the north is the National Museum of Archaeology and Anthropology, containing an outstanding collection of Mexican archaeological treasures. Most of these are Aztec in origin and were excavated in or around Mexico City, but there are also many from nearby Teotihuacán and from Palenque, Yucatán, and other areas. The so-called Aztec Calendar Stone is here. The National School of Fine Arts, formerly the San Carlos Academy, is close to the National Palace, on the east. It contains a valuable collection of paintings, mainly Mexican or Spanish in origin.

On the south side of the Zócalo is the City Hall (Palacio Municipal), which was established in 1532. The present building, in colonial style, dates from 1720–1724 (with additions in 1909), and has a valuable archives section.

East and north of the Zócalo are the old

headquarters of the Universidad Nacional, for which the University City on the outskirts of the capital was dedicated in 1952; the baroque Escuela Nacional Preparatoria (National Preparatory School); and the Secretaría de Educación Pública (Department of Public Education), which occupies a building erected in 1922. Nearly every modern Mexican artist of renown has contributed to the murals in one or more of these buildings. The old building of the Escuela Nacional de Medicina, dating from 1736 and formerly the headquarters of the Inquisition, is near the Secretaría de Educación Pública.

Among the many churches in this area are those of La Santísima Trinidad, dating from 1677, with a fine Churrigueresque façade; La Soledad de la Santa Cruz, completed in 1731; Loreto (1809–1816), by the architect Manuel Tolsá; and Santo Domingo, dedicated in 1736, with a baroque exterior and Churrigueresque interior.

The Avenida Madero and the Avenida Cinco de Mayo, two important business thoroughfares, extend parallel westward from the Zócalo, leading to the Palacio de Bellas Artes. This ornate, white marble building contains the Teatro Nacional, smaller auditoriums, and galleries. The Teatro Nacional, used for concerts and plays, contains a well-known curtain of glass mosaic designed by Dr. Atl (Gerardo Murillo), depicting the panorama of the Valley of Mexico overlooked by Popocatepetl and Ixtaccihuatl.

The Alameda, the largest and most beautiful of the public parks, covering some 40 acres, begins on the western side of the Palacio de Bellas Artes. It is intersected by pleasant walks, shaded by trees, and adorned with flower beds and fountains.

The southern side of the Alameda is bordered by the Avenida Juárez, in effect a continuation of the Avenida Madero and like it lined with fashionable shops, hotels, and office buildings, many of radically modern architecture, although interspersed with older structures. The monument to Benito Juárez, erected in 1910, is at the midpoint of this side of the Alameda, facing the Avenida Juárez. At the end of the latter avenue is the *glorieta* (circle) containing an equestrian statue of Charles IV of Spain, by Manuel Tolsá.

A few blocks north of this point are the bulky Monument to the Revolution, and facing it, the Frontón México, center for *aficionados* of pelota or jai alai, and also the railroad stations.

Running southwest from the *glorieta* of Charles IV is the Paseo de la Reforma, one of the most beautiful avenues in the world. It was designed by Maximilian, who named it the Boulevarde Imperiale. The Paseo is the fashionable afternoon drive and promenade. It is over two miles long and is lined on each side by double rows of trees, beneath which are footways and at their sides stone benches. It expands at regular intervals into three other *glorietas* containing statues of Columbus, Cuauhtemoc, last of the Aztec emperors, and a monument to the independence of Mexico. The houses, hotels, and apartment buildings along the Paseo are almost exclusively of modern architecture.

The Paseo extends to the foot of Chapultepec, a rocky height rising abruptly from the level of the surrounding valley. A beautiful park, set with gigantic trees, encircles the base of the rock. The castle crowning the hill was built between 1785 and 1840, and was occupied by Maximilian and Carlota and was long the official home of presidents. It contains the National Historical Museum, with post-Hispanic historical collections, relics of Cortés, Hidalgo, Juárez, and Maximilian, among others, and portraits of the Spanish viceroys. The view from the front is regarded as one of the most beautiful in the world—the long vista of the Paseo to the city standing in the center of the valley encircled by high mountains from which rise the snow-capped peaks, Ixtaccihuatl and Popocatepetl. In the park at the base of the rock there is a monument to the Mexican cadets who fell in 1847 while defending the hill from the assault of United States troops.

Suburbs.—Besides a number of residential and industrial suburbs, several are of special interest. Guadalupe Hidalgo (officially Gustavo A. Madero), two miles north of the capital, contains the celebrated shrine of the Virgin of Guadalupe, the patron saint of Mexico. Here the treaty of peace following the war with the United States was signed in 1848. At Popotla, west of the city, is the famous Tree of the Dismal Night, beneath which Cortés is said to have sat and wept over his losses after fighting his way out of Tenochtitlan in 1520. Coyoacán, south of the capital, is even older than Mexico City. Cortés made it the seat of government while he superintended the rebuilding of the conquered city. The house in which he lived is still standing. At Xochimilco, also south of the city, are the famous floating gardens.

Drainage Problem.—Mexico City is built on the site of settlements by the Aztecs, which were on islands in shallow Lake Texcoco at nearly the lowest point in the valley. From the earliest times, therefore, there has been danger of inundation, and the sponginess of the subsoil presents a special building problem.

There were five lakes within the valley, all of which, with the exception of Texcoco, were above the level of the city. In times of heavy rains their waters sometimes overflowed the banks and, having no outlet through the surrounding mountains, found their way to Lake Texcoco which, being only two or three feet below the level of the city, rose sufficiently to flood it. Before the Spanish conquest and for some time afterward dikes were built about the city to keep the flood waters out, but these proved ineffective. Inundations occurred on an average once in 25 years. In 1607, the Tajo de (Cut of) Nochistongo was begun through the mountains, as an outlet for the flood waters of the highest lake in the valley which was 13 feet above the level of the city. In 1629 there was another flood and the city was flooded until 1634. Not until 1789, when the Tajo de Nochistongo was completed, was the city freed from the menace of deluges, but the menace of malaria and epidemics remained.

In 1885 a gigantic canal and tunnel project was jointly undertaken by the city and national government. It was designed to serve a twofold purpose: to control the waters of Lake Texcoco, thus removing all possibility of future inundations, and to be a continuation of the city's sewerage system. It starts just east of the city, where it joins the network of city sewers. It extends to the mountains, a distance of 43 miles, connecting with Lake Texcoco on its way. It pierces the mountains by a tunnel nearly seven miles long, and beyond the mountains is continued as a canal for several miles, finally emptying into a tributary of the Pánuco, which carries the city waste to

the gulf. This gigantic undertaking was completed in 1900 and ranks among the truly great enterprises of modern engineering. The city can never again be seriously inundated and it is now provided with an effective sewerage system.

The water supply is taken mainly from the western mountains and from several natural springs at the foothills to the south of the city. The latter supply is now largely used as potable water. There are also a thousand or more artesian wells, mainly privately owned.

Due to the softness of the subsoil, many of the heavier buildings have sunk or sagged, a process intensified by draining the waterlogged soil of its fluid. This is true not only of such older buildings as the cathedral, but also of the Palacio de Bellas Artes, which was begun in 1900 and has sunk about six feet. Tall modern buildings, such as apartment houses, are being built on the displacement principle, so that they "float" in the soft soil.

Industry.—There are hundreds of industrial establishments, most of which have sprung up since the advent of electric power, there being no other cheap fuel, or waterpower, available. The main industries are iron foundries, tanneries, manufactures of glass, paper, cement, textiles, tobacco products, chemicals, and petroleum products, automotive assembly plants and tire factories, and food processing and canning.

History.—The history of Mexico City begins with the foundation of Tenochtitlan by the Aztecs, who settled on islands in Lake Texcoco in the early part of the 13th century (see AZTECS). According to tradition, they were directed by an oracle to settle where they saw an eagle perched on a cactus, devouring a serpent; hence this scene on the national coat of arms.

In the center of Tenochtitlan was the great temple, approximately on the site of today's Zócalo. Before the arrival of the Spaniards the first rude houses, standing on piles and built of mud and rushes, had been replaced by buildings of stone, and Tenochtitlan had become the chief city of an extensive empire (see MEXICO—*Prehistory and Pre-Hispanic History*).

It has been estimated that this city had a radius of over a mile. It was intersected by canals, and connected with the mainland by causeways. During its conquest by Hernán Cortés in 1521, it was largely destroyed. No trustworthy record exists as to the size of the population at this time. One contemporary writer states that it was 500,000; another, 30,000.

On the same site in 1522, Cortés began the building of the Spanish city. But so many changes have been made since then that the city of today retains hardly a trace of the city founded by Cortés. In 1600 its population consisted of 7,000 Spaniards and 8,000 Indians. In 1746 it had a population of 90,000; 50 years later one of 113,000.

Under the Spaniards, Mexico City was the capital of perhaps the wealthiest province of the Spanish Empire; mansions, churches, and public buildings were erected in profusion and lavishly embellished.

So completely has the capital dominated the country during the colonial and independent periods that the history of Mexico City is practically the history of Mexico. It has ever been the object of contending parties; yet during the struggle for independence it was almost untouched, Agustín de Iturbide, making his entrance peacefully in 1821 at the head of the insurgent forces. Even during the chaotic period which followed, the capital suffered little, as regime followed regime. In 1847 there was severe fighting between United States and Mexican forces at Churubusco, Molino del Rey, and Chapultepec, south and west of the city, but Gen. Winfield Scott entered the city practically without opposition on Sept. 14, 1847.

It was captured by the French in June 1863, and Maximilian was installed by them as emperor soon after. The Mexican Liberals recaptured the city in June 1867, bringing the empire to an end.

The present aspect of much of the city is due chiefly to Maximilian's projects for beautifying his capital, to buildings and improvements during the long regime of Porfirio Díaz (1884–1911), and to the expansion, increasing prosperity, and building programs dating from the middle and late 1920's, the period following the Revolution of 1910, and thereafter.

During this revolutionary period, in 1913, the city was the battleground between followers of Francisco Madero and anti-Madero revolutionists, and a limited number of buildings suffered during ten days' shelling and street fighting, February 9 to 18.
